Examination at 11 A.M.—Pulse, 120; respiration, 18. Chloroform odor to breath, which friends state has been noticed several times before when bowels were constipated, but not so intense as at present. Seems slightly delirious at times. Pain continues in paroxysms. Examination of abdomen negative, except increased fulness over seat of pain. Ordered magnes. sulph., ʒ ij. q. 1 h., till bowels move. Codeia, gr. ⅛.

1.30 P.M.—Has been slightly drowsy, but is now quite excited; pain severe, pulse very rapid and weak. Stimulants ordered. Breathing has become suspiciously deep, but not increased in frequency.

2.30 P.M.—Enema given without result.

5.30 P.M.—Severe pain. Codeia, gr. ⅛. Breathing labored, eighteen to minute. Is only semi-conscious. Temperature, normal; pulse, 150.

8.30 P.M.—Has passed no urine since morning. Catheterized, and thirty-two ounces obtained, which contains ten per cent. of albumen, estimated by precipitate on boiling.

Subsequent examination showed gr. 1½ to ʒ j. by weight, and glucose gr. xv. to ʒ j. Faint reaction of urine with tr. ferri chlor. No acetone by Ralfe's test. Patient cannot be fully aroused. Chokes in swallowing.

Has now taken nearly ʒ ij. of magnes. sulph. and one seidlitz powder without result, and purgatives were now discontinued.

9.30 P.M.—Rectum cleared of semisolid fæces. Stimulants given hypodermatically. Is fully comatose. Oxygen was now administered by continuous inhalation, the delivery tube being passed well back in the mouth. Chloroform odor, which had become so intense as to pervade the entire cottage, was markedly diminished, but the respirations are deepened. Rigidity of lower limbs and tendency toward adduction noticed. Skin is distinctly warm to touch.

Midnight.—Oxygen has just been suspended for a short time. Respirations have a cycle of frequency, which is inversely as the depth, with total duration of twenty to forty-five seconds. Pulse, 150. Examination of chest negative.

1 A.M.—Oxygen acts promptly as a stimulant to the pulse, but has no good effect on the breathing. Incontinence of urine. Bladder found empty when catheterized. Cups applied over kidneys. Temperature in axilla 102½°. Other conditions unchanged. Oxygen continued at intervals merely as a cardiac stimulant. No evidence of cyanosis. Swallows fluids in small quantities if placed well back in pharynx, but with a good deal of choking. Pupils symmetrical, react well, but undergo a rhythmical contraction and dilatation. Every third expiration intensified into a loud groan, while the others are simply noisy. They are chiefly thoracic; the groaning expiration follows a peculiar spasmodic inspiration of extra depth, which calls into play the accessory muscles in the neck, and results in a bending back of the head and a depression of the lower jaw. Respirations 24 to minute.

4 A.M.—Temperature in axilla 105⅕°. All treatment discontinued. Examination of chest negative.

5 A.M.—Temperature in axilla 106⅖°. Pulse failing rapidly. Respirations are diminishing in intensity; less moaning. No cyanosis.

6 A.M.—Patient died quietly. No convulsive movement, except that eyes opened widely for a few seconds and then closed. No autopsy obtained.

In this case the marked depreciation in the patient's condition had made his family very anxious to have him removed from their summer cottage to the city, that he might be under closer medical supervision. Had this been done, the journey would probably have been held accountable for the fatal attack. Preparations had been made to perform transfusion, in case the use of oxygen was unsatisfactory; but in an isolated country cottage, and with all the attendants so prostrated by nervous excitement as to make them unavailable, this was out of the question, even had the pyrexia not been considered to be a contra-indication.

The effect of the oxygen on the pulse and the breath odor suggests further trial of this agent as an auxiliary in treatment.

Diabetic coma is too often regarded as simply a very interesting complex of symptoms ending in death.

There are numerous recorded instances of symptoms presenting too close a coincidence with those of diabetic coma, in its earlier stages, to permit us to doubt their nature, which have disappeared spontaneously or by treatment, and left the patient no worse off than before. And it is to these cases that we are chiefly indebted for an opportunity to study the causes and treatment of this condition.

Foster,[1] Schmitz,[1] Frerichs,[1] Jaenicke,[1] Jaksch,[2] Quincke,[2] and others give histories of diabetics which detail the appearance of symptoms of general prostration, malaise, anorexia, headache, vertigo, vomiting, abdominal pain, delirium alternating with drowsiness or stupor; deep, labored respiration, aromatic odor to breath, associated with the excretion of a substance in the urine giving the red reaction with chloride of iron. In certain cases the resemblance of the delirium to alcoholic intoxication is specially noted, and in a few cases there was recovery after a stage of complete unconsciousness.

Several of the patients died at a later period with the usual comatose phenomena, which, up to a certain point, were identical with those of attacks they had previously recovered from.

It would be interesting to repeat some of these histories in detail, but the limits of this paper do not permit. It must suffice to consider a few of their most striking lessons.

The most obvious is, that in them the history of previous fatigue or over-exertion rarely appears.

---

[1] [illegible]

[2] Arch. f. [illegible]

They were, for the most part, well-pronounced cases of diabetes, under treatment in hospital by the usual dietetic measures, and in almost every case the starting-point seems to have been in some digestive derangement. Now, diabetics as a class are not apt to suffer from the ordinary symptoms of dyspepsia, at least while on a mixed diet; and if we look into the particulars of these cases we shall find, in the great majority of instances, either that the patient, while pursuing a more or less restricted diet, suddenly consumed a large quantity of sugar-forming food, and was then seized with vomiting, etc.; or that the diet had been suddenly and sharply restricted, and in a few days anorexia, headache, drowsiness, etc., appeared; or that the attack began after a prolonged deprivation of carbohydrate food, with somewhat insidious onset.

Of the first class Schmitz narrates two cases which recovered quite promptly when the intestinal tract was thoroughly emptied by large doses of castor-oil, although the condition had reached a high grade of intensity. In these cases it is interesting to note that the sugar disappeared from the urine during the attack, and did not return till convalescence began.

Of the second class Jaenicke and Ebstein give cases which show a sudden onset of nervous symptoms immediately following a change to absolute meat diet, and disappearing promptly when the diet was relaxed.

Of the third class, in which the strict diet was tolerated for a considerable time, there is no good instance of the development of very intense symptoms. Usually the patient rebelled when the early symptoms appeared, or the treatment was modified with good results; sometimes because the physician feared coma, having regard to previous experience, as in a case by Jaenicke;[1] sometimes on general principles, in view of the evident derangement of digestion, and the onset of extreme prostration.[2] If we attempt to ascertain the influence of diet upon the one hundred and thirty odd cases of fatal issue, we are met by the fact that in only a very small number is any precise account given of the dietetic management. In a few of the cases it is noted that death seemed to have been accelerated by too strict dieting.

Cyr[3] mentions a case in which, while under treatment, various threatening symptoms appeared from time to time, and were relieved by allowing a moderate quantity of carbohydrate food, and thereby increasing the excretion of sugar and water.

Ebstein[4] makes a similar observation, and explains it in much the same way that uræmic manifestations are accounted for. Some toxic substance is developed within the organism, under certain influences which we cannot define, but so long as the kidneys are functionally active and the excretion of urine is not unduly diminished by treatment or otherwise, this agent is eliminated freely; when it is very rapidly formed or is retained the severe symptoms follow.

A careful survey of the many circumstances under which coma and its allied symptoms have arisen, as well as the conflicting results of experimental and pathological investigation, can only lead to the conclusion that there are many and diverse conditions producing symptoms having a general resemblance. Yet there is one element which seems to stand in a causal relation, whether it be primary or secondary, to the greatest number of cases, and that is gastro-intestinal derangement.

The digestive apparatus, it is true, seems to adapt itself to almost any conditions that are imposed upon it, provided the modifications be made gradually. But let an unusual strain be put upon this mechanism, which has been overburdened with work, poorly supplied with nervous force, and nourished by an abnormal blood, whether the strain be irregular nerve-supply from excessive bodily fatigue or mental excitement, the confinement of the patient to a hospital ward, abrupt changes of diet, a persistence in some unusual food-supply, or the advent of some complicating pathological process, then will this violence in all probability determine the faulty transformation which results in the toxic agent.

The further history of the case will depend on the relation which exists between the quantity of the morbid product and the ability of the organism to eliminate it.

Such, at least, seems to be the fair inference to be drawn from the clinical histories.

Heretofore but very brief allusion has been made to the frequent presence in the urine of a certain something which gives a reddish-brown reaction with ferri chloridum.

This reaction is now believed to be due to diacetic acid.

Concerning the origin and significance of this and certain other related compounds, a good deal has been written, and numerous painstaking observations have been made with very discordant results.

The following statements may be given as comprising the facts of most practical interest with reference to diabetic coma:

These bodies seem to result from a decomposition, occurring probably within the alimentary canal, which, except perhaps in minimum amount, is always pathological. The exact conditions which determine this decomposition are unknown, but they seem to be most favorable during early life. The excretion of these products has been occasionally observed in a variety of morbid conditions, among which are acute alcoholism, the exanthemata, pneumonia, cancerous cachexia, sulphuric-acid poisoning, meningitis, typhoid fever, and most frequently in diabetes mellitus. While bearing no constant relation to any special class of cases, or form of diet or medication, this phenomenon is more frequently observed in severe cases, in young patients, and in those pursuing a strict nitrogenous dietary.

Their appearance in diabetes may not necessarily be accompanied by any change in symptoms; yet a large percentage of cases of coma arise in patients who are excreting substances in the urine.

No special significance can as yet be attributed to the presence or absence of acetone, when diacetic acid is present, and occasionally acetone may be present in urine which does not react with ferri chloridum. Neither of these substances will reproduce the symptoms of diabetic coma, if administered experimentally.

I do not think it is permissible to draw any inference from the innocent nature of excreted substances, as to the relation of their appearance to the morbid phenomena. Neither albumen nor glucose are poisonous, and yet their excretion is closely related to serious symptoms.

The chemical transformations which occur within the animal body are usually much more complex than the formulæ which we employ to represent them. It is by no means improbable that during a decomposition, some of the ultimate products of which we detect in the urine, toxic influences are developed which are the true cause of the symptoms.

Routine tests with ferri chloridum should be made at short intervals in all cases of diabetes.

Add a few drops of a solution of ferric chloride to the urine in a test-tube, and if from excess of phosphates the iron is precipitated in sufficient quantity to obscure the reaction, filter the contents of the tube, and add a few more drops of the reagent to the clear fluid; if diacetic acid be present, a coloration results varying from a light claret to an opaque reddish brown. This color is dissipated by heating, and will not appear if the urine has previously been boiled. The solubility of the color thus obtained in ether is insisted upon by Jaksch as an additional test to exclude the presence of salts of formic and acetic acid, which give a similar reaction in other respects. But it does not seem that from the standpoint of clinical significance this distinction is of much importance.

[2] Harnacke, [illegible]
[3] Archives Gén. de Méd., 1878, vol. 1, p. 542.
[4] Deut. Arch. f. klin. Med., xxviii.

When the above reaction is obtained it is desirable to ascertain the presence or absence of acetone by some of the approved methods, in order that the record may be complete.

These tests are of importance on account of the pathological theories which the presence of these substances has suggested, and also because they afford in a great many cases valuable warnings of impending danger. But there is great need of further observation to determine just how great that value is, and also how frequently and under what other conditions these bodies may appear in the diseased, and perhaps also in the healthy organism.

During the past three months I have examined about three hundred specimens of urine with this object. Among them were six cases of diabetes, which were pursuing an uneventful course. Of these six I obtained a reaction in one case only, and that in four specimens covering a period of ten days. Tests for acetone made by the iodide of potassium and caustic potash method gave no result either in the urine or in the expired breath. There was no albuminuria.

These specimens were obtained through the kindness of the house staff, from a patient at St. Luke's Hospital, a man, aged thirty-two, diabetic for about fifteen months, who had been on pretty closely restricted diet, with codeia in doses gradually increased from one and one-half to eight grains daily, for about six weeks. During this time all the symptoms had improved, the patient had gained in weight, the polyuria had been reduced from about two hundred to one hundred ounces daily, and the sugar percentage from five to two and one-half.

During his stay in the hospital he had short periods of marked drowsiness, but this symptom was not present at the time the above tests were made. There were no dyspeptic symptoms, and the bowels were regular. He left the hospital soon after. (See note at end for further history.)

The five other cases were all adults, having from two and one-half to seven per cent. of sugar and well marked polyuria. They were either on ordinary or very slightly restricted diet, all able to be up and about, and in fairly good condition. The results in these cases were entirely negative.

The other cases included of special pertinence a pneumonia in the first stage, a case of advanced cancerous cachexia, an acute alcoholic gastritis, several cases of acute follicular tonsillitis, a dilated stomach, a large number of the usual dispensary cases of chronic dyspepsia, one case of chronic uræmia with prominent gastric symptoms, and the remainder were from the usual routine examinations. With the exception above noted no reaction was obtained. I regret that the number of specimens obtained from children was small, and that no cases of the exanthemata were available.

Unquestionably there are deaths, preceded by coma, in diabetes which can be explained by manifest lesions of the chief viscera; their symptoms and progress need no special comment. However, it is probable, from the endless variety seen in comatose cases, that there are many which are difficult to class in the absence of a careful autopsy; and it is to such cases that we owe a good deal of the confusion which marks any discussion on this topic.

The diagnosis must be reached by a careful process of exclusion, which will often be attended with great difficulties, and sometimes, in the absence of previous history, it may be impossible. Cases seen for the first time during an attack, and nothing being known of the previous history, have been mistaken for alcoholism, hysteria, peritonitis, cerebral injury, uræmia, narcotic poisoning, or internal hemorrhage, according to the symptoms most prominent. When we recollect that there may be suppression of urine and absence of glycosuria, the mistakes are easily accounted for.

The ordinary treatises on the practice of medicine seldom give more than a passing notice of this subject, and omit it altogether from the discussion of differential diagnosis in diseases liable to be complicated by coma.

In the treatment of diabetes mellitus, with reference to the possibility of this complication, there are certain precautions which seem to be desirable from the considerations which have been advanced.

The most prominent of these is the necessity of paying a close attention to the condition of the alimentary tract; the avoidance of sudden changes in dietetic management; the allowance of a certain, though small, quantity of carbohydrate food in those cases in which a fair trial has demonstrated that strict diet does not completely arrest the glycosuria; the free allowance of fluids in all cases, for there is everything in favor of considering the polyuria as a conservative factor. All sudden changes in mode of life are dangerous.

When complications arise the diet should be relaxed, particularly when the ferric chloride reaction appears.

On the appearance of symptoms suggestive of a comatose attack, in addition to the above, free and repeated purgation should be employed, guarded by suitable stimulant measures. For the relief of pain opium must be used on ordinary principles.

For those cases in which the condition has advanced to any marked degree, repeated transfusions of salines, or, perhaps better, of blood, the continuous inhalation of oxygen, the administration of antifermentatives and stimulants seem to offer the best hopes, judging from the partial successes which have been attained. To these, measures which promote diuresis should be added.

Although the treatment of this condition has been very unsatisfactory, yet, in view of the many cases which have recovered from a perilous position, there are none which should be abandoned, even after coma has set in.

The great fatality of diabetic coma, the obscurity of the causes which bring about its occurrence, and the importance of estimating at their proper value the indefinite symptoms which seem to be premonitory should urge us to closer observation in all cases of diabetes. The terminal phenomena are interesting, but much less valuable than a careful record of the previous history; and it is in this particular that the existing literature is barren.

How many patients live daily on the verge of comatose catastrophe, and escape it by the happy chance of judicious treatment, or perhaps because they disregard all recognized rules, we shall not know until we can read the natural history of the disease in fuller details.

NOTE.—Since the completion of the above paper, and only a few days ago, I secured the address of the patient referred to above as showing the ferric chloride reaction while pursuing an apparently very favorable course of the disease, and undertook to hunt him up for the sake of making further tests of the urine. I then learned that he died about three weeks after leaving the hospital, with symptoms which tend to confirm the value of the test referred to.

The following history was obtained from his family, and great care was used in framing the questions to avoid suggesting symptoms:

After his return from the hospital, on March 9th, he continued the hospital diet very carefully. It is said that the only lapses were in the use of an occasional oatmeal cracker.

March 15th.—His appetite suddenly failed, and he felt out of sorts generally. Nevertheless he paid a visit to some friends in a part of the city about two miles distant from his home, making use of the horse-cars, so that he walked in all about one mile. On his return in the evening he was very prostrated, ate nothing, and passed a very restless night, complaining of a burning pain in the epigastrium. Whether he had eaten anything unusual during the day could not be ascertained.

March 16th.—He was very drowsy, sleeping a good deal of the time, and during the intervals walking restlessly about his room. Ate nothing. Pain continued;

very great diuresis; passed over a pailful of urine during the day. Marked "heavy" odor to breath, which the relatives, when asked if there was any special odor they could compare it to, promptly mentioned a liniment which on examination proved to be the ordinary chloroform liniment. During the night continued to suffer from pain and restlessness.

March 17th.—In the morning able to go down-stairs and across the street to get shaved. Returned in a very dull and tired condition. Took a little mutton-chop, and soon after extreme epigastric pain came on, followed by vomiting, which did not bring relief. In the evening had "a sudden spell of weakness," with extreme abdominal pain, and was believed to be dying. Breath odor very intense. Panting respiration. No coma. Bowels have not moved for two days. A physician who was called in gave some powders which relieved the pain, and recommended a diet which was by no means as strict as the previous.

During the following ten days the patient slowly improved, and by the end of a week was able to be about again. The breath odor disappeared.

On March 28th, and the two days next succeeding, the bad symptoms returned. No cause assignable for the onset. He was much inclined to sleep, but too restless to remain quiet. Complained that the room was close, wanted the windows opened, and finally insisted on going out, although the weather was very stormy, because he "must have a breath of air."

On one of these days he behaved in an unusual manner, was very jovial, mimicked some peculiarities of speech of a neighbor, sang a good deal, etc.

During this time the breath odor returned. For twenty-four hours before his death, which occurred on April 1st, he had severe pain and vomiting, jumping out of bed and crying out during the paroxysms. His breathing was very labored. Skin cool, natural in color. Great diminution in quantity of urine passed. Some incontinence. Spoke in a noisy way, addressing persons who had been dead some time, evidently believing them to be present, until one hour before his death, when he sank into coma.

Physical examination made during his stay in the hospital failed to give any evidence of visceral lesions.

BRAIN EXHAUSTION.[1]

By N. H. BEEMER, M.B.,

FIRST ASSISTANT PHYSICIAN, ASYLUM FOR THE INSANE, LONDON, ONT., CAN.

During the past ten years the question of the changes which take place in the physical structures concurrently with intellectual action has given me much serious thought, and until the last few months this question has been involved in such uncertainty that there was very little satisfaction in contemplating it. Various eminent authors have written on this subject under various names, such as nervous asthenia, nervous exhaustion, neurasthenia, nervous weakness, American nervousness, cerebral hyperæmia, etc., and while all these terms are appropriate, I prefer to follow Dr. J. Leonard Corning, and shall employ the simple term brain exhaustion.

According to a novel computation by a German histologist, who has been calculating the aggregate cell forces of the human brain, the cerebral mass of average size is composed of three hundred millions of nerve-cells, each being an independent body so far as its vital relations are concerned, and living a separate life individually, but subordinated to a higher purpose in relation to the function of the whole organ. In order to gain a lucid understanding of our subject, we must fix clearly in our minds the idea that one or more of these brain-cells is called upon to do work whenever there is any intellectual action; and we must also bear in mind that every cell, like every muscle, has a certain limit to its capacity for work. While we sometimes forget the fact, still we all know that the blood-stream is the repository of vital energy, and we must also admit that from this source each organ, with an elective faculty peculiar to itself, selects only such elemental combinations as it requires for the evolution of its own vital forces. Each vital organ of the body must necessarily use up, in the performance of its function, the equivalent of a certain amount of assimilated nourishment; and if we may, for the sake of argument, regard the whole muscular system of man as one vital organ, we may then say that in the case of the working-man—the day-laborer—this organ, meaning his muscular organization, uses up the equivalent of more nutriment than any other of his vital organs. But this demand for muscular nourishment does not take place in the brain-worker, whose muscular system is comparatively inactive. In his case it is rather the brain that takes from the blood the greatest amount of those nutritive elemental combinations suited to its need, and represented by a large amount of the food ingested. It has long been understood that in the performance of brain work there was some kind of molecular action going on within that organ, but the exact nature of it is the point that has been so perplexing, and the want of some rational theory has been the reason for so much vague speculation. Whether right or wrong, Dr. Corning, of New York, in his recent work, has set forth a very common-sense explanation of what really takes place. He regards the molecular action as one of contraction of the brain-cells, in a way similar to that of the contraction of the muscle-cells in muscular work. A given cell, or set of cells, may, if well and regularly supplied with nourishment, contract and expand to the least perceptible extent in the evolution of brain force, for several hours in succession, without any special damage; yet if the work is continued beyond the inherent strength of the nerve-cell, exhaustion must be experienced by the cell, just the same as when a given set of muscles is exercised beyond the limit of their endurance. Continued use of one set of muscles will soon determine an increased amount of blood supply, so that the waste may be repaired, and the same thing takes place when one set of cells is long exercised in the brain. Vigorous and continued mental exercise will soon call an increased supply of blood to the brain to repair the waste which is taking place there. If this increased supply of blood to the brain should be demanded by the overworked organ for any great length of time, the vessels themselves will not at once return to their normal size upon cessation of the work, but will at least temporarily remain enlarged, and thus it is that we have the cerebral hyperæmia which Dr. Hammond has written about, and which he was inclined to regard as the essential pathological condition of brain exhaustion. Prolonged intellectual work will noticeably elevate the cerebral temperature, and this elevated temperature is accompanied by a more or less hyperæmic condition of the vessels; if the hyperæmia be only of a few hours' duration, it is merely physiological, but when it remains for days together it becomes pathological. But voluntary thought is not the only thing that proves exhausting to the brain; indeed, a considerable degree of intellectual action is what makes the brain strong and vigorous; but it is the hurry and worry that seem to take away from the brain-cells their store of strength so rapidly. To understand how it is that hurry in intellectual work tires so much, let us go to physical work for an illustration. If a man walk a mile leisurely, he will only feel a healthy glow as the result of the moderately rapid expenditure of physical force; but let him run only half a mile at the top of his speed, and he will feel so fatigued that he can hardly speak or breathe, and still he has only covered half the distance, but in a shorter time. So, likewise, if a man engage at a moderate rate in mental labor for an hour or two, he will feel well and fresh and the better for it; but if he work for only half an hour at the highest intellectual pressure, he will find himself fagged out and exhausted. The very rapid contraction of the

[1] Read before the London, Ontario, Medical Association.

brain-cells is not their normal way of working, and they soon exhaust the elements which are stored up within themselves, and failing the supply from the blood-stream, which can only take place slowly, they are left on the verge of bankruptcy. Worry operates differently by reason of its continuousness; the contractions may not be rapid, unless as in the case of a man receiving some appalling news, but the contractions are continued at every intermission from other intellectual work. The rest, which in another man will follow the completion of his daily mental work, will not come to the man who is worried, for as soon as the brain is done with the daily work, the worry begins and allows no rest to the brain-cells.

If these brain-cells should be weakened or exhausted by too prolonged intellectual work, they become less capable of resisting the onset of worry, which they might more successfully do if strong and rested. We all know that when tired out mentally trivial things will worry us, which would be passed over almost without a thought when we are fresh and strong; that which seems to us of slight importance in the morning will grow to mammoth proportions of seriousness by evening time. If those tired out brain-cells come under the influence of worry, and are thus stimulated to further contractions, when they should be resting and receiving a store of nourishment for the morrow's work, it does not seem surprising that they are unfitted for their work when the morrow comes. Now, so long as the output of vital force by any single organ does not differ too greatly from that required by the remaining tissues of the body, all will be found to go well; but when one organ is called upon for too long a period to exercise its function, we shall observe two phenomena. In the first place, those elements of the blood required for the maintenance of the function of this particular organ will become more or less completely exhausted; and, in the second place, the organ will borrow those needed elements from any other organs that contain them. Relative to the first of these phenomena Dr. Maudsley says: "Poverty and vitiation of blood may certainly play a weighty part in producing mental disease, as they do in producing other nervous disorders. Lower the supply of blood to the brain below a certain level, and the power of thinking is abolished; the brain will then no more do mental work than a water-wheel will move the machinery of the mill when the water is lowered so as not to touch it." And so, likewise, if we impoverish the blood by abstracting its building elements, or if we vitiate it by the addition of noxious elements, we make it an unhealthy medium for the supply of that help which the brain requires to do healthy work. In reference to the second of these phenomena—the borrowing of needed elements from other organs—we may find some of the best illustrations of this kind of plundering in those individuals who are inordinate brain-workers. It happens not infrequently in such persons that the fatty, and also the muscular, tissues are reduced to a surprising degree, so much so, in fact, that the individual will exhibit a considerable amount of emaciation. He will observe his own poorly nourished condition, and will commonly fall into the error that forced physical exercise is what he requires, whereas his real want is physical as well as mental rest.

Only a few weeks ago I was talking with a young man in this city on the subject of recreation. Knowing that he was an earnest and hard-working student, I was somewhat curious to learn what he did in the way of physical exercise. He said: "Well, doctor, I don't suppose I am doing what is right; for although I take no physical exercise, I feel too tired when I reach home from the office in the evening to engage in anything of that kind." Now this young gentleman is a graduate in Arts of Toronto University, and he spends his time during the day in the work of a law office, and his evenings in preparing himself for the examinations of the Law Society; and he, in these ways, expends every day all the nervous energy which his food supplies, and if he were to take forced physical exercise to any considerable extent, he would injure rather than benefit himself. But there is another way in which some of this emaciation of brain-workers may be accounted for. I refer to the malassimilation incident upon deficient nervous supply to the stomach. When the brain is tired out, and a large meal is taken into the stomach, it is impossible that sufficient nervous influence shall be conducted to the stomach for the perfect digestion of the meal, and hence we commonly find that when this practice has become a habit, the patient will suffer from all that train of evils resulting upon indigestion. Many men and women are thus treating themselves for a tired stomach where the primary cause is an overwrought brain. To further illustrate the exhausting effect of purely intellectual action, I will mention a few typical cases.

A previously healthy and robust young man, who was teller in a bank in this city, and through whose hands a large amount of money passed daily, told me that while he simply attended to the work of the bank he could do it with a self-conscious feeling of ease and accuracy. He saw, however, an opportunity of improving his business relations by a knowledge of short-hand, and he accordingly set himself to work in earnest to learn it. After tea every evening he would spend three or four hours in close study upon this subject. All went well for a fortnight, but at the end of a month he began to suffer from headaches and a sense of mental confusion, and he lived in daily dread of making a mistake in his cash. In six weeks the misfortune which he feared overtook him, and his error cost him several months' salary. Easier work in another department of the bank, where there was less continuous mental strain, together with fewer hours' work at short-hand in the evening, served to restore him speedily to his former health and spirits.

One of the most eminent and deservedly popular ministers of the Presbyterian Church in Canada to-day works so hard with his brain, while delivering his regular weekly discourses to his congregation, that his flannels and linen are saturated with perspiration, and have regularly to be changed after leaving his desk; and he is not one of those men, either, who pound the book and saw the air with their hands. The result of this prodigal expenditure of nervous force is that every year his general health becomes so enfeebled that he is forced to take a long vacation, and every few years he has to take a transatlantic trip.

Ex-President Arthur, a few weeks before he left the White House, said to a friend: "I think I am an unusually strong man, yet after I have been receiving visitors for two hours I am as limp and as deficient of muscular strength as that rag. They strip me of all my nervous force."

In Mr. Dolby's book on "Dickens as a Lecturer," he confirms the opinion that Dickens brought on his death by overwork and excitement. He says that the reading of the murder scene in "Oliver Twist," by Dickens, would bring the reader's pulse up from 72 to 118, and that on these occasions he would have to be supported to his retiring-room and laid on a sofa for fully ten minutes before he could speak a rational or consecutive sentence.

Shelley, who was poorly while writing "The Cenci," said he believed that the mental labor connected with its production proved a fine antidote to the nervous sedatives which he was taking at the time, and that the mental excitement "kindled the pain in his side as sticks do a fire."

When Wordsworth was engaged in composing the "White Doe of Rylstone," he received a wound in his foot, and he observed that the continuation of the literary labor increased the irritation and pain of the wound; whereas by suspending his work he could relieve himself of these unpleasant symptoms, and absolute mental rest was finally requisite to his perfect cure.

Southey perpetrated industrial suicide by his incessant study and mental labor. A biographer says of him: "His

busy brain wore itself out, and the workman could but wander, without purpose and without power, among the books which he had gathered with patient love around the walls of his writing-room."

And we all know, if we will only stop to look at the question in the right light, that the lives of such men as the late Lord Lytton, Earl Beaconsfield, and Thomas Carlyle furnish ample evidence of intense mental and physical sufferings which were the direct outcome of mental over-work.

From what has already been said, it may be readily inferred that certain classes of society will be especially subject to brain exhaustion, and while no classification is strictly accurate, I think the majority of cases may be classed among one of the following: 1st, Persons engaged in science, art, or literature; 2d, those engaged in politics; 3d, those in commerce, exchange, and speculation; 4th, those who are too laborious among students and scholars; and 5th, mothers with small children and a large share of domestic care.

We shall now have to pass rapidly on to the clinical history, and we shall find that the chief symptoms of brain exhaustion may be classed, for the sake of convenience, into psychical and physical. Under the head of psychical we shall find restlessness during the day, and more or less wakefulness during the night. This restlessness is peculiar in itself, and if long continued we call the individual fidgety and fussy, as he will make a great bustle over nothing, or next to nothing, and besides this he is never satisfied with the work in hand. This restlessness is also accompanied by intense and excessive irritability; the patient will imagine himself imposed upon when such is not the case, and he will fancy himself slighted when nothing of the kind is intended; he will conjure up some fancied wrong, and attach the cause of it to the first one who comes in his way, just as often his friend as his casual acquaintance. He will also magnify the slightest oversight into a grave offence, and for the moment it will overpower all other considerations of the mind. "This extreme irritability is one of the most characteristic features of the disease, and is absolutely beyond the control of the patient; the paroxysms of anger may be extremely brief in their duration, or may continue for several hours. During their continuance the subject manifests a morose and sullen attitude toward all with whom he may be thrown in contact. Sometimes he is revengeful, and concocts extravagant and fantastic plots against those who are supposed to be inimical to him. At others he is lachrymose, and disposed to look upon himself as a martyr—as one misunderstood by his fellow-mortals."[1] The sleeplessness at night is accompanied by a series of unfriendly and harassing thoughts passing rapidly, and sometimes unconnectedly, through the mind, and is followed naturally enough by a state of drowsiness for half the next day; and when the sleep does come it is generally disturbed by horrible and wearisome dreams.

The faculty of registering impressions is often materially deranged; sometimes names of familiar places, persons, and objects are temporarily forgotten, and the utmost effort fails to recall them. The will often exhibits a marked impairment, and daily duties are performed in a cursory and indifferent manner, in spite of an earnest desire to do them well. Mental confusion, somewhat resembling that semi-consciousness preceding sleep in the healthy person, is frequently experienced. There is also a morbid curtailment of the power of mental concentration. I do not here refer to absent-mindedness, for there the mind is engrossed with some other subject; but rather a mental state in which the patient finds it impossible to devote himself continuously and vigorously to any given subject. This lack of mental concentration is particularly characteristic of brain exhaustion, and the medical observer will find this true in conversation with his patient.

[1] Brain Exhaustion, with some Preliminary Considerations upon the Physiology of Dreams. By J. Leonard Corning, M.D. New York: D. Appleton & Co. 1884.

Among the more prominent physical symptoms in brain exhaustion is pain in the region of the vertex and superciliary arches, and also at the back of the neck; and in different patients entirely different forms of mental occupation will excite the pain. In one man, reading for a few minutes will not only be followed by the pain, but also by a sense of exhaustion; in another, writing for a short time will produce these symptoms; and in still another, continued conversation on any question requiring much attention will be followed by like results. Photophobia is common in this class of patients, and reading by gas-light is especially painful to the eyes, so that colored and other glasses are often called into use. The sensibility to certain sounds is sometimes abnormally developed, so that the squeaking of a door, or the rumbling of a cart, or the sound of certain musical instruments may prove intolerable. The skin of the face bears a pallid and unhealthy appearance, and the eyes lack that lustre which belongs to the healthy and well-rested brain; altogether the expression of the countenance can only be described by the term aged.

Derangements of the function of the stomach play a prominent part in prolonging and aggravating brain exhaustion, and I am satisfied that in many cases the brain is primarily at fault where the blame has been laid upon the stomach. In order that a good meal, say at midday, may be properly digested, the stomach must have sufficient nervous force sent to it; but it often happens that the nervous system has already been overworked in the morning, and should have rest before taking up a new load; the man, however, hurries from his office or store to the restaurant, where he will either continue the business of the morning in his own mind, or lay out plans for the afternoon's work. In this way he will expect his brain to continue its work at a high pressure, and he will also impose upon it the additional burden of sending sufficient nervous influence to his stomach to digest a full meal, perhaps imperfectly masticated. A locomotive is caused to stop occasionally to take on fuel and water, but man is not as good as that to his own brain. Is it any wonder, then, that after a while the stomach, which is at the same moment both starved and overloaded, should rebel? And when it does rebel, we can easily see that the condition of the brain is made infinitely worse, for then the supply of nutriment to the brain is largely cut off. The cry of the stomach in its distress is likely to direct the attention of the patient, and sometimes that of the practitioner as well, to that organ, and the character and quantity of the food is then so regulated that the poorly nourished brain is still further impoverished; and the stomach itself is not relieved till the patient is sent away for a trip where he really escapes the mental work and worry of his daily duties at home.

The symptoms of indigestion are, in many respects, so similar to those of brain exhaustion, that anyone may be easily forgiven for confounding the two conditions, especially as those of exhaustion are so soon followed by those of indigestion.

There is almost always some cardiac disturbance, and this is sometimes one of the earliest symptoms to excite the apprehension of the patient. Emotional excitement, even if only slight, will cause the most distressing palpitation, and change of posture, as from sitting to standing, will greatly increase the number of pulsations. This tumultuous action of the heart often gives the patient much real concern, but the stethoscope reveals the absence of any organic lesion.

The kidneys are more or less affected, and the urine is sometimes scanty, and at other times greatly in excess of the normal quantity and limpid; the phosphates are generally found in abundance in the urine of exhausted brain-workers. We know that cerebral irritation may produce diabetes, and we know that emotional excitation and worry will produce a sudden and temporary polyuria; but, so far as I have been able to ascertain,

very little is known of the effect of brain exhaustion upon the kidneys.

While emaciation of the muscular structure is the common condition, it is by no means constant; the physical inactivity which an exhausted brain sometimes enforces upon the muscular system may prevent the oxidization of the fat-globules which have been previously stored away, and we thus have the apparently anomalous condition of a fat man with exhausted brain-cells. Those cases where very little emaciation has taken place are, I believe, the most difficult for satisfactory treatment; but in them, like all other cases, there is a perfect intolerance for exercise—anything like a long walk is regarded by the patient as a species of cruelty.

And now we come to the question of treatment, and I approach it with a certain amount of trepidation, because of our natural tendency to pay slight regard to what is simple, and to attach much importance to what is complex. Our veteran teacher in medicine, Dr. Austin Flint, said, in his address to the New York State Medical Association, a few months ago, that fame would attend that author who would write a work on the non-medicinal treatment of diseases. A few weeks afterward an eminent Canadian author said he believed that the erection and endowment of a thoroughly equipped hospital where medicines should never be used, unless an occasional anæsthetic, would be of the greatest possible benefit to mankind and to the science of medicine. I think, gentlemen, after we carefully consider it, that you will all agree that the spirit of these observations is especially applicable to the treatment of brain exhaustion.

There are three factors of primary importance to brain action, namely, first, the condition of the brain-cell; second, the condition of the cerebral blood-stream; third, the physiological relationship between the cell and the blood-stream. In order that the brain-cell shall perform its function properly, it is necessary that intracellular nutrition shall be physiological both in respect to quality and quantity of nutriment. After the cell has exercised its function for a certain length of time, the energy of its contraction gradually diminishes until there is more or less complete suspension of activity. Now, if the blood-stream were capable of effectually neutralizing the waste which takes place in the cell *during* its functional activity, we should have nervous expenditure on the one hand, with an equal nervous reimbursement on the other, and there would remain no necessity whatever for rest or sleep. As it is, however, during our waking hours waste outstrips supply, and it is only when the mental work, and even consciousness itself, has been temporarily suspended that the blood-stream can supply the deficit. I believe we have here the key to the scientific treatment of this affection. *Rest* by prolonged *sleep*, as recommended by Dr. J. Leonard Corning, is the main point to be observed, and along with it a generous supply of nourishment. Of course, rest also means cessation from mental and physical work, and relief from worry. Sleep means an increased period of unconsciousness daily, not induced by hypnotics. Nourishment means a liberal amount of good food which can be easily assimilated, such, for instance, as rich and carefully prepared soups and beaf-tea; and this food should be administered as often perhaps as four or five times daily. Above all, plenty of time must be allowed for recovery, and it is well to explain this to the patient at the outset. A condition which has been induced by years of overwork cannot be expected to disappear in a week or a month.

Two other facts should be taken into account in this connection. One is that some men's brains are capable of evolving mental force much more rapidly than others, and consequently waste takes place in these cases much more rapidly. The other fact is that different sets of cells are engaged by different subjects, and hence the rest which is experienced by the student who turns from one subject to another, as, *e.g.*, from mathematics to classics.

A CASE OF POISONING BY SULPHATE OF MORPHIA—RECOVERY.

By LLEWELLYN ELIOT, M.D.,

ALTHOUGH the record of cases of poisoning by opium and its alkaloids is very extensive, I have no apology for adding the report of one more. The treatment of such cases is always a subject of great and varied criticism; many pursuing a very gentle course, others, like myself, pushing to extreme measures immediately. No one is competent to judge the merits of a course of treatment unless he be associated in the case, for what may appear as an imperative measure to the attending physician would seem but a foolhardy procedure to one not so situated. As illustrations of this, note that in one case reported by Fothergill there was one grain (.067 grm.) of sulphate of atropia, administered hypodermatically, to antagonize twelve to seventeen grains (.8 to 1.143 grm.) of opium, with success; and again, where Dr. J. H. Clarke[1] administered gr. $\frac{1}{1000}$ (.000446 grm.) every half-hour to counteract thirty grains (2 grms.) of morphia; after the third injection the pupils dilated and general improvement began. In the case of Dr. Clarke the dose of atropia to antagonize one grain of morphia was gr. $\frac{1}{1500}$ (.0000446 grm.). This appears to be a ridiculously small dose; but, considering the favorable result, it was sufficiently large, notwithstanding the stomach had not been evacuated. To establish the lethal dose of sulphate of morphia would be a hard task. Death has followed the administration of gr. $\frac{1}{4}$ (.011 grm.), and babies of two years have taken with impunity doses of gr. $\frac{1}{18}$ (.0041 grm.), frequently repeated. Some weeks ago I was called, during the night, to attend a gentleman, seventy-four years of age, and within the space of three-quarters of an hour he had taken one grain (.067 grm.). Having reached this limit I did not deem it safe to give more, although there did not appear the least evidence of the action of the drug. I might add that, in this case, the patient had on several occasions obtained marked relief from doses of gr. $\frac{1}{8}$ (.008 grm.).

H——, male, white, aged thirty-four, of fine physique, at six o'clock on the evening of May 16, 1885, while under the influence of alcohol, took fifteen and a half grains (1.033 grm.) of sulphate of morphia with suicidal intent. He was seen in five minutes; his face was much flushed, conjunctivæ congested. He had been given ℥ij. (2.67 grms.) pulv. ipecac., which failed to act. The following solutions were made:

℞. Atropinæ sulphat ..... gr. ij. (.133 grm.)
Aquæ destillat..... ℥j. (4 c.c.)

M. Sig.—Ten minims hypodermatically, to be repeated in half an hour, if necessary.

℞. Apomorphinæ hydrochlorat.. gr. j. (.067 grm.)
Spt. vini rectif..... ℥ss. (2 c.c.)
Aquæ destillat ..... ℥jss. (6 c.c.)

M. Sig.—Ten minims hypodermatically.

The apomorphine injection (gr. $\frac{1}{150}$, .0055 grm.) was first administered, followed immediately by the atropine (gr. $\frac{1}{30}$, .022 grm.). This was ten minutes after taking the poison. He was fast sinking into a stupor, pupils contracted to a point, and breathing becoming stertorous. In ten minutes more he was profoundly insensible, not aroused by severe shaking and vigorous paddling; pupils enormously dilated; face, neck, and ears very much cyanosed; respiration labored, superficial, hissing, and stertorous, but ten in a minute; pulse very feeble, regular at one hundred and forty beats; jaws locked. He had failed to vomit. A large cork was inserted between the teeth, he was turned upon his side, his tongue drawn forward, and

[1] [illegible]

artificial respiration employed; death seemed imminent. A messenger was despatched for assistance and a battery. Respiration improved and face assumed a natural color under the application of the interrupted current—one pole placed over pit of stomach, the other at varying points over chest and neck. At a quarter to seven, ten minims (.67 c.c.) more of the atropine solution were inserted subcutaneously. Respiration increased to sixteen, and became full; pulse at wrist one hundred and forty, and feeble; heart-beat strong. He continued in this condition until half-past seven, when Dr. James E. Morgan arrived. With his assistance, and with much difficulty, I introduced the stomach-tube, and injected about a quart (1,024 c.c.) of water; this was thrown off in a few minutes. This procedure embarrassed his breathing very much; it again became shallow, abdominal, and superficial; pulse became intermittent; heart's action feeble; face cyanosed; death seemed imminent. Under the application of the battery and the hypodermatic injection of ten drops (.67 c.c.) of aquæ ammoniæ, diluted with one drachm (4 c.c.) of distilled water, he again rallied. During all this time the tongue and fauces were very dry and hard. At nine o'clock the stomach-tube was again introduced. After thoroughly washing out the stomach, a drachm (4 c.c.) of aromatic spirits of ammonia in two ounces (64 c.c) of water was injected. This was allowed to remain. At half-past nine he was removed to the Emergency Hospital, where the house staff—Drs. Wright, Roy, Taylor, Morgan, and Hoskins—rendered valuable assistance. At eleven o'clock one grain (.067 grm.) of caffeine citrate was inserted in the arm; this was followed in fifteen minutes by gr. $\frac{1}{100}$ (.00067 grm.) sulphate of atropine, as the effects of the former injections seemed to be wearing off. Battery again applied. Through the stomach-tube introduced gtt. xx. (1.333 c.c.) aqua ammonia in one ounce (32 c.c.) distilled water, without ill result. Pulse too intermittent to count, ranging from sixty to ninety-six per minute; respiration superficial, stertorous, and eighteen. At twelve a pint (512 c.c.) of strong infusion of coffee, with two grains (.133 grm.) caffeine citrate, was injected into the bowel; this was retained. At two A.M. he was with difficulty aroused; at three he took a few swallows of coffee; this was rejected. Was walked about for some time, when, at four, he was taken to his home, where he undressed himself and went to bed; sight not good, but he was quite sensible.

℞. Cerii oxalat,
Ingluvin..... ãã gr. xxx. (2 grms.)
M. Div. in pulv. no. vj. Sig.—One powder to be given if nausea or vomiting occur.

17th, 10 A.M.—Nervous; complains of soreness of body. Potassium bromide ʒ ss. (2 grms.) at night. Has not passed urine; mouth dry, pupils natural.

18th, 10.30 A.M.—Has not slept since he recovered from effects of morphine, nor has he any inclination to sleep.

℞. Sodii bromid..... ʒ ijss. (10 grms.)
Potass. bromid..... ʒ iv. (16 grms.)
Tinct. cannabis indicæ... ʒ ij. (8 c.c.)
Aquæ destillat., q. s. ad... ʒ iv. (128 c.c.)
M. Sig.—Dessertspoonful, in water, every four hours.

20th.—Much improved, no inconvenience about stomach. Has slept comfortably; put on full diet; point of injection of the apomorphine indurated, those of the ammonia injections same.

23d.—Doing well; poultice to indurations.

28th.—Discharged from treatment.

Remarks.—The points of interest in this case are many, the principal ones being the large amount of sulphate of atropine used in such a short time, but the continuance of the symptoms show it not to have been sufficiently large; the short time—ten minutes—required to produce the effects of the morphine, and the correspondingly short time for the atropine to manifest its effects. The amount of alcohol which he had ingested aided materially in assisting the toxic effects of the morphine, as it had produced congestion of the brain, which was intensified by the morphine. Whether the apomorphine was antagonized in its action by the atropine I do not know, but incline to the belief that it was. Von Boeck[1] writes, in cases where emetics fail to act, it is "because the excitability of the extremities of the sensory nerves in the mucous membrane of the stomach is so greatly reduced by the narcotic poison that no reflex movements can be excited." Again he writes: "Therefore, useful as emetics may be in themselves, we must not forget that, even under the most favorable circumstances, they may decidedly promote and aggravate the collapse which is imminent in consequence of the action of the poison." His statement respecting apomorphine is clear and positive, as will be seen from the following extract: "I once had an opportunity of observing a severe case of morphine-poisoning, in which apomorphine failed to induce vomiting in a patient who was lying in profound sopor, but the collapse shortly after the injection became far more decided than before." Had there been administered in the first instance two-thirds of a grain (.044 grm.) of the atropine sulphate in place of the one-third (.022 grm.), and this followed in half an hour, if necessary, by a sixth (.011 grm.), or even another third (.022 grm.), I firmly believe that the length of the narcotism would have been very much shorter; the pulse and respiration would have shown but little the effect of either poison. In the treatment of narcotic poisoning it is a question in my mind whether beating, thumping, and lashing are of any avail. They may be vigorously pursued, and are in every such case, but would it not be better to do away with such cruelty and at once proceed to the administration of proper antagonists. I assisted in a case of opium-poisoning in Baltimore City, some years ago, where the flesh was cut away with a black-snake wagon-whip while we waited for remedies. For hours the poor fellow was walked, trotted, pulled, and beaten from one end of the warehouse to the other. He recovered, notwithstanding the violence of the treatment. Thomas G. Morton, in a case reported, bled in a large quantity, after which eight ounces (256 c.c.) of defibrinated blood were thrown into the saphena vein on the right foot. The patient died, but, so far as I can remember, was benefited by the operation. This case occurred in the Pennsylvania Hospital some years ago, but I do not recall the journal in which it was reported. Dr. D. Tod Gilliam[2] reports a case of opium-poisoning in a female, sixty-four years of age, in which he practised transfusion of milk into the radial vein with apparent success. As a means of combating the exhaustion consequent upon violent and excessive physical treatment, this is an excellent measure. In the case referred to the patient died. With respect to the caffeine treatment of narcotic poisoning—within narrow limits this drug is antagonistic to morphia; still I should not be willing to sacrifice a patient to a fair trial of it. From its being readily decomposed by water, it is ineligible for hypodermatic use. Tanret[3] suggests as a stable preparation, dissolving caffeine in a solution of benzoate or salicylate of sodium. Its relative solubility is: in 100 parts of water, 160 parts of absolute alcohol, and 220 parts of ether.

To Prevent taking Cold.—Dr. Brown-Séquard says that a "cold" usually results from the reflex influence of cold air upon the sensitive nerves of the nucha. He proposes to overcome the peculiar sensitiveness of these nerves by blowing with a pair of bellows upon the neck, using first warm air, which is to be gradually cooled, until the patient can stand any sort of a draught (of air, not of liquid) without sneezing.

DEVIATIONS OF THE NASAL SEPTUM.

By S. O. VANDER POEL, JR., M.D.,

After the exhaustive paper read before the Fellows of the Academy last year, it would scarcely seem expedient to again open this subject, were it not that an operation suggested for the correction of this deformity had not received the attention from the profession it would seem to deserve.

The numerous methods of procedure that have been devised for the correction of deviations of the nasal septum, and the diversity of opinion that exists in the minds of surgeons, would seem to indicate that at present no generally accepted plan is adopted in the treatment of these cases.

In dealing with this deformity it will best suit our purpose to divide the subject into three heads: 1, Deviations of the cartilaginous septum, with deflections of the end of the nose—usually attributable to traumatism; 2, deviations of the bony septum, accompanied by the high-vaulted palatine arch, as was first pointed out by Duplay and subsequently elaborated by Jarvis; and 3, a combination of the first and second varieties, where the deformity exists in both the bony and cartilaginous structures. Under this head would also be included the so-called sigmoid deviations, where both nasal cavities are more or less obstructed by a crumpled condition of the septum.

I would invite your attention for a few moments, this evening, to the consideration of Roberts' operation, which is applicable principally to the first of these three divisions, namely, deviations of the cartilaginous septum with deflections of the nasal tip, as well as to many of the osseous deviations accompanied by cartilaginous displacements. In these the cartilage is the structure most at fault, and when it is corrected the bone will frequently be found not to offer sufficient obstruction to prevent good drainage and a free respiratory tract. Roberts thus describes his operation: "With a scalpel introduced through the obstructed nostril, I perforate the cartilaginous septum at its upper and back part, and make a long incision downward and forward; this permits me to push the whole cartilaginous septum to the left (assuming the obstruction to be in the left nostril), and overcome to a great extent the lateral deformity. To retain the parts in position I introduce a steel pin, one inch and a quarter long, in the right nostril, and pass it completely through the anterior and upper segment of the divided septum, near the columella. Having the movable portion transfixed, I carry the head of the pin to the left, and with it the anterior part of the nose, and retain it there by embedding the point deeply in the immovable cartilaginous septum and mucous membrane at the back part of the left naris. In other words, I incise the deformed cartilage and pin it in position very much as you would pin a flower in the button-hole of a coat."

The most important indication to meet in any of the operative methods for the correction of a deviated septum is the retention of the parts in their replaced position. The tendency for them to resume their faulty posture is so strong that considerable force is required to retain them; even after the lapse of some weeks, in cases which at first gave evidence of perfect restitution, the septum will gradually work its way back as soon as the retentive apparatus is removed.

Adams[2] and Jurasz[3] attempt to overcome this resiliency of the septum by crushing it with forceps, and then retaining it by a splint and hollow plugs. Those who have employed this plan are aware of the many annoyances and difficulties constantly met with—the clogging of the tubes with the secretions, or by granulations sprouting into their ends, thus rendering them impervious to air, the difficulty in replacing them after removal for cleansing, and, on the other hand, their frequent expulsion in the effort of coughing, as the inflammatory swelling subsides. These considerations have induced many operators to abandon the procedure and seek easier and more effectual methods.

Other prominent means employed for overcoming this condition are the ablative punch of Blandin[1] for removing a portion of the tissue, the stellate punch to overcome the resiliency, the galvano-cautery, and the snare.

The objections urged against the punch, where no effort is made to correct the position of the deformed septum, are, that although it permits of a somewhat freer respiratory tract through the fistulous opening, still, thorough drainage, so necessary to good nasal hygiene, is not obtained, the secretions being pent up in the nostril posterior to the obstruction, there to decompose and perpetuate the accompanying catarrh. In aggravated cases the cautery and écraseur would seem insufficient, for although by means of them the usually existing hypertrophies can be removed, permitting of freer respiration, still the septum remains out of position, and the danger of perforating it while cutting through the tissues is always to be thought of. The various forms of retentive apparatus, such as splints and trusses, aside from being unsightly and thus confining patients for a week or so, are in most instances very painful, and require to be frequently removed and readjusted.

These considerations led me to give Roberts' operation a somewhat extensive trial, and in properly selected cases, more especially those complicated with a deflection of the end of the nose, it has yielded very satisfactory results.

The operative procedure followed, in some eighteen cases treated, consisted in introducing a sharp-pointed bistoury into the nostril in which the convexity presents itself, and perforating the cartilage at its superior border, the point of the instrument being met in the opposite nasal cavity by the little finger of the operator; thus guarded, the knife is carried in a vertical direction to the floor of the nares, passing through the point of greatest convexity. We thus have the septum divided into two segments, an anterior and posterior, instead of a superior and inferior, as described by Roberts, the advantage being that the pin is given a better leverage in bending the tip of the nose into position, and it is not possible for it to slip through the incision, as it frequently does when the cut is horizontal. In making the incision it is well that the handle of the bistoury be slightly elevated, in order to bevel the edges of the cut surfaces, so that when the septum is pressed back into position the two segments will override, and being held there by means of the pin, unite in this new position.

In cases where there is simply a luxation of the inferior border of the septum as the result of traumatism, this incision would not seem necessary, and instead the Adams forceps may be employed to break the false attachment and press the cartilage back into position, the pin being used to retain it. When, however, the deviation is congenital, and is accompanied by the high-vaulted palatine arch, or the sigmoid deflection is present, in which both nostrils are more or less obstructed, it may be necessary to ablate some of the tissue with a punch before the pin is introduced. In these cases the difficulty seems to arise in a redundancy of septum, the high-vaulted palate not giving it sufficient space to develop vertically, but crowding it to one side. It then becomes necessary to remove the redundant portion.

The other modification that suggested itself during my first cases was the employment of a shield in the obstructed nostril, to prevent the pin from ulcerating through, and also to give a broader leverage. The necessity for it was suggested by finding, in several instances, some days subsequent to the operation, that the septum bulged

[1] Read before the Section on Laryngology and Rhinology of the New York Academy of Medicine, March 20, 1886.

[3] Berlin klin. Wochenschr., 1882, No. 4.

[1] Compendium de Chirurgie Pratique, t. iii., p. 33.

into the nostril both above and below the pin, owing to the fact that the cartilaginous septum, especially in its central portion, is exceedingly thin, its apparent thickness being due to the two layers of mucous membrane covering it upon either side. In order to overcome this tendency, I have had a small elliptical metallic shield constructed, with an eye attached to the centre of its flat surface, through which the pin passes. The septum is perforated by the pin through the anterior of the two segments made by the incision, at right angles to the axis of the nostrils, and the point made to pass through the eye on the shield, which is held in the convex nostril over the line of incision. The point of the pin is then carried backward until the bony septum is reached, when by crowding the cartilage a trifle beyond the median line the point is made to impinge against the lateral wall of the vomer on the side in which it entered—that is to say, the point enters and emerges in the same nostril. If, for instance, it be the right naris that is obstructed, the pin should be introduced through the left; it then pierces the eye on the shield and is carried straight back parallel to the axis of the floor of the nose, and made to rest in the mucous membrane on the left side of the bony septum—not necessarily passing into the left nasal cavity. The principle upon which it acts is that of a lever of the second order, the power being represented by the head of the pin, the weight by the convexity of the septum, and the fulcrum by the bony septum.

If it should be found, when the pin is in position, that the tip of the nose is deflected too far in the opposite direction, it may be corrected by grasping the pin by means of forceps within the nostrils, and bending the end of the nose until it is in proper relation to the face.

In selecting a pin, it is necessary to obtain one of not too high a temper, in order to avoid its breaking when bending the septum into position, an unfortunate accident which may lead to considerable difficulty in extracting it. The pin used is made of plated steel wire, about four inches in length, and with a temper which permits it to bend slightly; a perforated shot answers for a head, which, when the pin is in position, is pinched, and so fastened at the tip of the nose, the excess of wire being cut off. The head of the pin is then lodged in the fossa at the tip of the nose, in order that the apparatus may be entirely hidden from view, and also to prevent it from dropping out.

Immediately upon the subsidence of the inflammatory swelling, which is usually slight, respiration through the previously obstructed nostril is possible, thus securing good nasal drainage and respiration throughout the course of treatment, a factor which contributes much to the comfort of the patient, other forms of retentive apparatus so obstructing the nares that free respiration is not possible. The pin is permitted to remain *in situ* two weeks, in order to give the wound sufficient time to unite.

Occasionally it may be found necessary, when the desired result has not been entirely secured by the first pin, to introduce a second. This procedure is analogous to the second operation so frequently done in strabismus. In placing the second pin in position it is not necessary to again administer ether, as a thorough application of cocaine will produce sufficient anæsthesia. The length of time which this second pin is allowed to remain is governed to a great extent by the amount of deformity to be corrected; usually, a week is sufficient.

In the first operations undertaken the hemorrhage was so profuse as to occasion considerable embarrassment, not only obstructing the view of the parts, but interfering with respiration. This is particularly annoying in children, where the nares are too small to permit of the introduction of the finger, and where it is necessary to see the parts perfectly to properly adjust them. To arrest this hemorrhage various measures have been employed, but that which has proved most effectual is the use of hot water combined with pressure. Two probangs are held in boiling water, and then thrust, one into each nostril, being at the same time pressed firmly together with the divided septum between them. Four or five minutes of such pressure, with perhaps heating the sponges a second time, will suffice to control the bleeding.

In conclusion, it may be remarked that the operation has proved itself more successful in deviations of the cartilaginous septum, especially those connected with deflections of the nasal tip, than any other measure advocated; and that the pin, as a means of holding the parts in position, has shown itself superior to other forms of retentive apparatus, being worn with less discomfort, and permitting of freer respiration and better drainage.

Clinical Department.

TWO CASES OF THORACIC ANEURISM.

Dr. Hobart A. Hare, of Philadelphia, reports the two following cases: Annie D—— came under his observation complaining of palpitation and severe pain in the chest and left arm when lying down. The pain began about three months ago, and has been steadily increasing. There was no history of syphilis or other trouble, except rheumatism; her father had suffered from this, and she had had an attack of acute articular rheumatism every winter for six or seven years, but her mother, two brothers, and a sister are free from it. Two brothers died of hydrocephalus before she was born. She had evidently had some cardiac trouble for years, but was nevertheless well developed for her age. She menstruated at the age of fourteen, about which time she began to work at weaving, at which she is still engaged. There was no history of traumatism or scarlet fever. Inspection of the chest showed an egg-shaped protrusion in the suprasternal notch, very expansile and bulging at each systole of the heart. The dilatation extended well up into the innominate artery for over an inch from its point of origin. Pulsation was strongly marked in all the vessels of the neck. The apex beat of the heart was in the sixth intercostal space about an inch to the left of the nipple. There was no distinct thrill over the precordial space, but it was well marked in the suprasternal notch and over the dilated portion of the innominate artery. On auscultation over the swelling there was heard a rough and soft murmur accompanied by a bruit. Over the aortic orifice was heard a double murmur—a short, sharp and rough systolic, and a long, softer, and more blowing diastolic. These murmurs were very distinct over the sternal notch, the diastolic murmur becoming intensified as the ear was carried down the sternum, reaching its maximum at the ensiform cartilage. Over the pulmonary orifice both murmurs were heard, but were somewhat muffled. Both were transmitted posteriorly to the left, but did not depend on mitral disease, as they were heard more loudly over the right scapular region than the left. Both murmurs could be heard in the vessels of the neck, the diastolic feebly. There was the typical "water-hammer" pulse, twenty-seven to the quarter-minute. Abdominal pulsation could be seen, but was not marked. Percussion revealed marked dilatation of the heart, accompanied by great hypertrophy. No dysphagia, dyspnœa, nor loss of voice. There was a marked difference in the time and force of the pulse in the two radials, the right falling behind and being shown by the sphygmograph to be altered in character. The interesting points in this case were the age, the double aortic disease, the enormous cardiac hypertrophy, the escape of the mitral valves, and the absence of dropsy and of many of the other distressing symptoms usually present in such cases. The patient was but seventeen years of age, while of sixty-nine cases compiled by Garland the youngest was aged twenty. Dr. Hare believes that there was a general dilatation of the aorta extending into the innominate artery, added to which was the recent formation of a small fusiform aneur-

ism from which arose the later symptoms—the pain, for example.

The second case was in a man twenty-eight years old, single, of good hereditary history, and who had never had any sickness, except a mild attack of rheumatism in the hip, and a gonorrhœa some nine or ten years before; he had never had syphilis, nor did he drink to excess. Two and a half years before coming under observation he had fallen from a car, striking full on his chest and face, after which time he began to suffer from dyspnœa, even without exertion. About two years ago he noticed a slight palpitation of the heart, followed by a feeling of a ball rising in his throat. For two years he had felt a throbbing in his chest, and for a year had felt the same sensation all through his body. Three or four months ago he began to experience difficulty in swallowing, and this increased until, on admission to hospital, he could swallow only liquid or soft food, the obstruction seeming to be about on the level with the cricoid cartilage. The voice was altered, apparently from pressure on the larynx rather than on the recurrent laryngeal nerve. There had been no cough nor spitting of blood. About the end of December he began to suffer from pains in the chest and right arm, becoming more and more severe, so as at times to make him very violent and even delirious, requiring hypodermics of one-hundredth grain of hyoscine to quiet him, morphine seeming to increase the trouble. He had double vision almost constantly, and even in his rational moments had visions which he said his mind told him were false. The pupils were widely dilated, the right more than the left. The left responded normally to light, but the right answered slowly, contracting for a moment and then dilating widely. This eye was more prominent than the other, and faint pulsation could be seen in it. The right arm was wasted and flabby. A heaving pulsation, synchronous with systole, was felt in the upper part of the chest, and the upper portion of the sternum was eroded. There was a tumor here extending about one and a half inch upward, and there was a distinct thrill perceptible over the aneurism. The patient's condition became so grave that an operation was decided upon, and Dr. Ashhurst ligated the right common carotid artery on a line with the cricoid cartilage. The man rallied well, but had several violent attacks which were controlled by hyoscine. The next morning he was rational, and had a good pulse, the right being less full than the left. The following night, however, he died from asphyxia, the aneurism pressing more firmly than ever on the trachea. This case is interesting from the age of the patient, the effect of hyoscine on the delirium, and the survival of the patient after ligation of the common carotid, only to succumb to asphyxia from pressure. No autopsy could be obtained. This case is reported by Dr. Hare through the courtesy of Dr. Pepper.

The Microbe of Hereditary Syphilis.—Kassowitz and Hochsinger state that they have discovered a special micro-organism, differing from the rods of Lustgarten, in the tissues of children suffering from hereditary syphilis. This microbe was found in the liver, pancreas, and osseous tissues, as well as in the skin (in pemphigus). It occurred in the form of streptococci arranged in chains. These were found in masses in the smallest capillaries, but were never seen in the cells themselves, being arranged around them. They were found chiefly in those parts in which the inflammatory process was most active, and seldom in tissues in which this process had run its course.

A Scarcity of Subjects for Dissection.—The University of Dorpat has hitherto received its supply of material for dissection from the hospitals and prisons of St. Petersburg, but an order recently made reserves all these subjects for the students in the Military Medical Academy in that city, and the authorities at Dorpat are at a loss for material for their own students.

Progress of Medical Science.

The Muscular Conditions in Flat Foot.—In a recent lecture by Professor Humphrey, published in *The Lancet* for March 20, 1886, the speaker called attention to changes occurring in the muscles which add to the difficulty of effecting a cure of the deformity. The muscles on the tibial and flexor aspect of the foot become relaxed and enfeebled, so that they fail to exert their proper contractile power, and cease to afford their proper support and to effect the normal movements of flexion and incurvation. Hence, he said, the antagonistic muscles—the extensors and the peronei—not being duly stretched or extended, fall into a contracted and irritable condition, which in no small degree aggravates the deformity and the discomfort arising from it. And the condition is further increased, or it may in some cases be excited, by the demand made upon these muscles to steady and brace the tarsus when the foot is placed on the ground and the weight of the body is thrown over it. Their state is similar to that of the muscles on the outer side of the knee in cases of knock-knee, and of those occupying the concavities of the spine in cases of lateral curvature, and is analogous, he thinks, to that of the flexor muscles in cases of disease of the knee and other joints. This state is relieved by rest, especially if the rest is combined with extension by means of a well-applied splint, but it soon returns unless the treatment is continued for a sufficiently long period.

The Etiology of Lateral Curvature.—Dr. E. H. Bradford concludes, as a result of some experiments made upon the cadaver (*Boston Medical and Surgical Journal*, March 18, 1886), that the deformity known as lateral curvature is the result of several factors, the chief being: 1, Superincumbent weight; 2, faulty attitudes, due usually to muscular weakness; 3, a condition of the bone structure of the spine rendering it incapable of resisting the effect of weight, analogous to that known as rickets of adolescence. The effect of weight on the head and shoulders would be, if applied in a vertical direction, to bend the spinal column forward and backward, but in flexible spines the superincumbent weight rarely falls in a direct line, and a lateral curvature follows. This is at first a physiological process, but it subsequently becomes, by the alteration in the shapes of the bones under altered pressure, a pathological change. The extent of the curve and its situation will be determined by the attitude habitually taken by the individual, and perhaps also by a difference in the resisting power in different parts of the column. The injurious effect of superincumbent weight in curving the spine is increased by the obliquity of the pelvis or the inclination of the shoulders so frequently taken by persons of weak muscular systems in sitting sideways and leaning. The curve is usually in the dorsal region, with the right shoulder raised, as the majority of people are right-handed. The distortion is one of growing years, and is more common to girls than to boys for two reasons, namely, that at the age when lateral curvature is usually seen first, girls grow more rapidly than boys, and their muscular system is less well developed, from the customary habits of life of girls in society. The effect of superincumbent weight upon a yielding spine in adult life, after the vertebræ have ceased to grow, is to cause an increase in the antero-posterior curve of the back.

Piperonal.—This is an aldehyde, corresponding to piperonilic acid, obtained as a product in the oxidation of piperina. It occurs in the form of small, white, prismatic scales, possessing a strong odor resembling that of vanilla. A small quantity placed upon the tongue produces a sensation analogous to, but more persistent than, that caused by mint, and it is more irritating to the mucous surfaces than is the latter. It melts at about

125° F., and at a higher temperature volatilizes without leaving any residue. When ignited the flame and smoke resemble the appearance of burning camphor. It is insoluble in cold water, but in hot water it melts, and looks like drops of oil; it dissolves readily in alcohol and ether. Dr. Riccardo Frignani has made a number of experiments with this substance (*Giornale Internazionale delle Scienze Mediche*, No. 2, 1886), as a result of which he states that it possesses both antipyretic and antiseptic properties. The antipyretic action is not of the most active or energetic kind, yet is sufficient in many cases. It is best given in fifteen-grain doses, repeated every two hours for three or four times a day, but much larger and more frequent doses are well borne. The most noteworthy disagreeable effects are nausea, eructations, and dryness of the throat. Its antiseptic action, however, the author states, is much more marked, and, since it is innocuous to the system, even when given in doses of one-half to one drachm, he believes that it is deserving of a high rank among drugs of this class.

Pilocarpine in the Relief of Itching in Jaundice.—A correspondent of *The Lancet* says he has used successfully, for this troublesome symptom, the hypodermic injection of one-tenth of a grain of pilocarpine. It caused some increase of the itching at first, but relief soon followed, and lasted from twenty-four to thirty-six hours.

Coexistence of Erysipelas and Scarlatina.—The coexistence of two or three forms of virus in the same individual is a question which is beginning now, in view of the new doctrines of bacteriology, to be an object of special study. Since Grancher published his observations on the coexistence in the same subject of measles and scarlet fever, it has come to be acknowledged very generally that one of the eruptive fevers can become grafted upon, or superadded to, another. In confirmation of these observations, Vigot reports a case observed by him in which the erysipelatous and the scarlatinous virus—or, in bacteriological terminology, the microbe of scarlatina and that of erysipelas—exerted their specific action upon the same individual at the same time. The patient was a girl, eleven years of age. The first disease to develop was erysipelas, which followed a contused wound near the eyebrow. In two days there appeared redness and œdema of the skin, the eyelids on this side were swollen and closed, and the temperature was 101° F. This condition lasted three days, when the signs of scarlatina—the sore throat and eruption—appeared, and the temperature rose to 103°. The scarlet fever followed its usual course and terminated in recovery. The erysipelas made no further progress. The conclusion drawn from this case was that the influence of the two diseases, or the two forms of virus, one upon the other, is nil, although possibly the course of the erysipelas may have been rendered more benign.—*Giornale Internazionale delle Scienze Mediche*, No. 2, 1886.

The Value of Lateral Incisions in Preventing Rupture of the Perineum.—Credé and Colpe strongly advocate a more free and early use of this measure than is generally made. This recommendation they base on an extended experience at the Leipzig Maternity Hospital, where they found, in 1,000 primiparæ, that out of 741 cases where lateral incision was not judged necessary, there were 104 ruptures, or fourteen per cent.; while in 259 cases where incision was made, and these, be it remembered, cases in which there appeared to be a probability of rupture, there were only 29 ruptures, or 10.7 per cent.; and of these not one was fatal. As regards the risk of infection, the writers do not find it greater where incision is made than in other cases; and they do not find that the operation leads to much weakness or deformity of the vulva, certainly not to so much as is produced by spontaneous rupture.—*Birmingham Medical Review*, March, 1886.

Hot Baths in the Treatment of Syphilis.—Dr. P. K. Kadkin records, in the *Meditsinski Sbornik*, No. 39, vol. xxii., a number of cases of syphilis in which he observed the effect of hot baths upon the elimination of mercury through the kidneys. As a result of his observations, he makes the following deductions: 1. Under the influence of hot baths mercury may be found in the urine of those syphilitic patients who are taking it. How long a time may elapse after the last dose of the drug has been taken before it appears is not definitely determined, but it does not exceed two months. 2. The method of inunction, obviously, cannot be employed in conjunction with hot baths, since the mercury would be immediately washed away. 3. After subcutaneous injections of corrosive sublimate the drug appears more quickly in the urine than it does after inunctions. 4. If the theory of Voit as to the mode of elimination of the syphilitic virus be correct, then this combination of hypodermic injections of the bichloride together with the simultaneous use of hot baths would seem to be the most rational, as in this way the mercury is the more speedily removed from the organism.

Vapor of Cubebs in Membranous Croup.—Dr. R. Couetoux relates, in the *Bulletin Général de Thérapeutique* of March 30, 1886, a case in which he obtained excellent results from the use of cubebs. The child was living under miserable sanitary conditions, and had also the disadvantage of being cared for by ignorant and careless parents. Various remedies had been tried, but without any beneficial results, and the child was apparently moribund, breathing with great difficulty, and able to like scarcely any nourishment. Dr. Couetoux then ordered about six drachms of powdered cubebs to be put in a vessel over a fire, and to be vaporized. This filled the apartment with a very strong and somewhat irritating, but not altogether unpleasant, odor. The child seemed to improve under this treatment, and it was ordered to be continued. But the following evening it was found that the parents had let the fire go out, and the child was apparently again at death's door. Another attempt was made, and this time the orders were obeyed, and the little patient began at once to improve and went on to recovery. A sister of this child, who was later seized with the same trouble, was also speedily relieved by inhalations of the vaporized cubebs. While not claiming any infallible specific action for this drug, the writer thinks that the results obtained in these cases would warrant further trial of the remedy.

Dystrophy of the Thumb-joints.—At a recent meeting of the Medical Society of London Dr. R. Maguire showed a case of dystrophy of the thumb-joints, in which inflammation of the carpo-metacarpal joints of both thumbs came on after the removal of two ovarian tumors in November, 1885. The arthritis had continued unabated, the veins about the joint were swollen, and there was an increase of temperature; grating between the arthritic surfaces could be obtained. The thenar eminences were a little wasted, but there was no reaction of degeneration, only generally diminished reactions to both currents. Menstruation had ceased since the ovariotomy. Pain was the first symptom in the left thumb; the right followed later. The reflexes at the wrists were perhaps a little exaggerated. Absence of rheumatism and gout, and the relation in time to ovariotomy, and the appearance of the disease when the joints were comparatively quiet, suggested a causal relation between the ovariotomy and the arthritis. In was connected not with congestion, but rather with anæmia of the genital regions. All treatment had proved of little avail. Mr. William Adams did not think it could be placed among the neurotic alterations in joints. Dr. William Ord believed that the case was one in which reflected "uterine" irritations were at work; the ovaries had been removed, but it was not known what the state of the uterus was.—*The Lancet*, No. 8, 1886.

A New Local Anæsthetic.—A crystalline substance has been obtained from the bark of the pomegranate, which, when placed on the tongue or other mucous surfaces, seems to produce a local anæsthesia similar to that obtained by the use of cocaine.—*American Druggist.*

Hysterical Sputum.—In addition to the known quantitative and qualitative alterations in the secretions and excretions in hysteria, Wagner has observed a special form of sputum, which is usually hemorrhagic in character, and may give rise to a suspicion of tuberculosis, especially if the patient has a cough and is run down in general health. This sanguinolent sputum is, he says, one of the most prominent symptoms of hysteria, and is to be distinguished from that of tuberculosis, of bronchiectasis, and of cardiac trouble, by its permanence and its uniformity. In quantity it amounts to from five to twenty-five drachms in the twenty-four hours. It may be occasionally of a gray color, but is usually reddish, and a little paler than ordinary bloody sputum. When kept for a time in a glass, a sediment forms of very small grayish particles. The sputum does not coagulate, and when examined under the microscope is found to contain fewer red blood-corpuscles than would be supposed. It contains also white corpuscles in greater or less abundance, ordinary pavement epithelium, and various forms of micro-organisms, but never any morphological elements which seemed to come from the lungs. The author was in doubt as to the origin of this sputum, but thought probably the blood came from little hemorrhages by diapedesis in the mouth; the presence of pavement epithelium would indicate a desquamative condition of the mucous membrane.—*Rivista Internazionale di Medicina e Chirurgia.*

Hematoma of the Sterno-cleido-mastoid in the New born.—Dr. Otto Küstner writes in the *Centralblatt für Gynäkologie*, No. 9, 1886, giving his views of the etiology of this affection. He says that it is true that hematoma of the sterno-cleido-mastoid muscle is caused by a stretching of the muscle, but it is not true that this stretching is the result of direct traction upon the neck during efforts at extraction of the fœtus. Such direct traction, he maintains, is incapable of producing a rupture of the muscular fibres or small vessels. This accident can result only from torsion, with the head turned to the same side on which the rupture occurs. In order to show that this was the only way in which the muscle could be sufficiently stretched, the author took the body of a child and, laying bare the sterno-cleido-mastoid, inserted three pegs into it. He then made direct traction on the head, flexed and extended it, and moved it from side to side without causing any separation of the pegs. Rotation of the head to the opposite side did not move the pegs apart, but rotation to the same side separated them so widely that a third peg could be easily inserted between either of the others. He concluded from his experiments, and also from clinical observation, that this accident could readily occur in normal labors, and was no evidence that traction, either instrumental or manual, had been made during the delivery of the child; and furthermore, that it could be produced during delivery either by the head or the breech.

A Support for the Body During the Application of Dressings to, and about, the Pelvis.—It is always a difficult matter to support the body of the patient, especially if he is etherized, during the application of a bandage around the pelvis. Dr. Moritz Schustler describes, in the *Centralblatt für Chirurgie* for March 13, 1886, an apparatus, devised by Professor v. Dittel, which would seem to furnish an excellent support in such cases. It consists of two round steel bars, about the length of a man and three-fourths of an inch in diameter, joined at one extremity by a cross-piece eight inches long. The united extremities rest on the bed or table, under the patient's shoulders, while the free ends, together with the feet, are held by an assistant. The buttocks and legs of the patient are thus supported by the bars, and any desired bandage can be readily applied. The iron rods being smooth, can easily be withdrawn without disturbing the dressings.

The Treatment of Erysipelas by Zinc Paste.—At a recent meeting of the Medico-Chirurgical Society of Montreal, Dr. A. D. Blackader read a paper on the use of zinc paste in the treatment of erysipelas, especially in infants (*Canada Medical and Surgical Journal*, March, 1886). He reported several cases of the disease, two of which have been treated by the application of white zinc paint over all the erysipelateous surface, in the manner recommended by Mr. Barwell with white lead. The same advantages were claimed for the zinc as had been for the lead, without danger of absorption of any poison, which, in infants, was perhaps to be feared with the latter. These advantages were immediate relief to pain and restlessness, followed rapidly, as a rule, by subsidence of pyrexia and arrest of the disease. The fact that erysipelas was a constitutional, and not merely a local, disease was not overlooked; but it was contended that, if by these local measures we moderate and assuage the local inflammation, we at the same time control at least some of the factors in the systemic disorder. Special advantages were claimed for the zinc treatment in infants. The paste is easily applied, dries quickly, and forms a complete dressing by itself, which cannot be soiled by the secretions, nor easily rubbed off by the restlessness of the infant. If desired, some disinfectant may be added. Soap and warm water readily remove the zinc coating after the attack is over.

The Surgical Treatment of Chronic Eczema.—Dr. Max Bockhardt recommends the following drastic treatment in chronic eczema. The crusts having been removed, the whole affected surface is scarified with a double-edged lancet in two directions at right angles to each other. After the bleeding has been checked, the surface is rubbed with wadding or charpie, soaked in solution of potash, until the upper thick epidermic layer begins to loosen. Then the potash solution is washed off, and the surface covered with diachylon ointment or olive oil. After twenty-four hours the dressing is removed, and a water-compress applied. The appearance then resembles an ulcerated surface, and the part is dressed, once in three days, with pyrogallic ointment or solution of nitrate of silver. The cure is complete in fourteen days to four weeks. Relapses do not occur, and the elasticity and flexibility of the skin are not affected.—*London Medical Record*, April, 1886.

Pigmentation of the Conjunctiva in Addison's Disease.—Dr. Armin Huber, assistant in the Zürich clinic, records a case of Addison's disease in which the conjunctiva was the seat of pigmentation. The pigment was deposited in one minute patch on the scleral conjunctiva of the right eye, above the corneo-scleral junction, and on each side in numerous spots along the lower margin of the cornea. The patient was forty-nine years of age, and presented well-marked bronzing of the skin, besides suffering from gastric symptoms so frequently met with in Addison's disease. The writer remarks that he is only aware of one other observation of the conjunctiva being pigmented in this disease, namely, in a case described in Gerhardt's clinic.—*The Practitioner*, April, 1886.

The Nettle as a Hemostatic.—M. Rothe has employed the tincture of urtica dioria, or the common nettle, to arrest bleeding from cut surfaces. It is not of value in arterial hemorrhage, but answers all the purposes to which iron styptics are applicable, and is free from the inconveniences of these latter preparations.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, May 15, 1886.

A NEW VIEW OF THE PATHOLOGY OF GOUT AND RHEUMATISM.

DR. P. W. LATHAM, Professor of Medicine at Cambridge, has recently delivered a series of lectures upon the pathology of rheumatism and gout, which are well worth the careful study of the physician. Professor Latham speaks from the standpoint of a physiological chemist, and it must be confessed that his chemical discussions are recondite and perhaps beyond the average reader.

Yet, after all, the basis of Dr. Latham's view of the pathology of gout, rheumatism, and perhaps of chorea and many neuralgias, is not obscure. It is simply the old enemy, uric acid, acting under various masks and irritating the nervous centres in various ways.

Dr. Latham believes that he has solved the problem of the origin of uric acid in the human body. In the human subject, glycocine conjugated with cholic acid is poured out as glycocholic acid, a constituent of the bile, into the intestine. After the bile has served its purpose in digestion, the glycocine as well as taurine are returned into the blood. These, together with the other amido bodies, leucine, and possibly tyrosine, the products of the digestion of albuminous food, reappear in the urine as urea; that is, the urine does not contain them, but its urea is proportionately increased. Now, these amido bodies, glycocine, leucine, etc., are probably carried by the portal vein straight to the liver, and from certain facts we are led to the view that among the numerous metabolic events which occur in the hepatic cells, the formation of urea from these bodies may be ranked as one. Suppose from some cause this metabolism of glycocine is interrupted, while taurine, leucine, etc., still undergo the normal changes with the production of urea, we should then have in the gland the two substances, glycocine and urea (or the immediate antecedent of urea), the conjugation of which by the gland (just as in the case of hippuric acid being formed from the conjugation of glycocine and benzoic acid) would produce hydantoic acid, which, dehydrated, would be converted into hydantoin.

Hydantoin is easily soluble, and so would pass on in the circulation to be combined elsewhere with two molecules of urea or with biuret, which is also soluble, to form ammonium urate.

Put in other language, Dr. Latham supposes that the glycocine which results from intestinal digestion and biliary secretion passes to the liver. It is there not metabolized into urea as it should be, but is conjugated with urea and converted into hydantoin; this passes on to the kidneys to be combined with other molecules of urea or biuret, forming urate of ammonium.

Defective metabolism of glycocine in the liver is therefore, according to Dr. Latham, at the root of the over-production of urates and uric acid.

This imperfect metabolism results from an inactive condition of the liver, due to overwork of its cells or deficient innervation. The uric acid circulating in the blood is generally eliminated by the kidneys, if these organs be sound, as is usually the case in young and middle-aged persons. If it is not eliminated, however, it may cause the various neuralgic and gouty symptoms, and generally by irritating a sensitive portion of the nervous system.

This is Dr. Latham's view of the pathology of gout.

Rheumatism is due also to the over-production primarily of glycocine, and then of uric and lactic acids; but in this disease, the glycocine originates in a different way, viz., through an excessive production in muscle. Through changes in vascular supply, due to the reflex or direct effects of cold, damp, etc., the muscular metabolism is modified, and glycocine and lactic acid are produced, the former passes on to the liver, spleen, and other glands, and ultimately becomes transformed into uric acid.

Having demonstrated his view of the pathology of gout and rheumatism, Dr. Latham lays down some very interesting practical rules which govern his treatment of these diseases. We cannot do better than present them in their entirety to our readers:

First, the true salicylic acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialysed and purified. An impure acid will very quickly produce symptoms closely resembling delirium tremens.

Secondly, give the acid without any alkali or base. A very good form is to mix one hundred grains with fifteen of acacia powder and a little mucilage. Allow the mass to stand and harden, and then divide into thirty pills.

Thirdly, place the patient fully under the influence of the drug—that is, let him have sufficient to produce cerebral disturbance, that is, buzzing in the ears, or headache, or slight deafness; with the development of these symptoms, the temperature and the pain in the joints will begin to decline. To an adult I generally administer three doses of twenty grains (six pills), at intervals of an hour, and, if the head remain unaffected, a fourth dose at the end of another hour; and then repeat the twenty grains every four hours, until the physiological effect of the remedy shows itself. In the majority of cases, from eighty to one hundred grains are enough. In severe cases, one hundred and forty to one hundred and fifty may be required. Afterward, about eighty grains a day are sufficient; and, as the temperarure declines, smaller quantities will develop their physiological effects, sixty or even fifty grains being then sufficient to produce cerebral disturbance. It would appear that, as long as the rheumatic poison is circulating in the system, the physiologi-

cal effect—that is, the effect it produces in the healthy organism—does not show itself; acting as an antidote, the greater the amount of poison, the larger must be the dose of the remedy; but, as soon as the formation of the *materies morbi* is stopped, then the excess of the remedy acts as it would in the healthy organism, and its peculiar physiological effects are developed. It is a very striking illustration of the difference between the therapeutic effect of a remedy and its physiological action.

Fourthly, give the patient from forty to eighty grains daily for ten days after all pain and pyrexia have passed away.

Fifthly, let the patient's diet consist entirely of milk and farinaceous food for at least a week after the evening temperature has been normal. On the other hand, if the patient have meat and soup, you may look forward with fair probability to a relapse.

Sixthly, take care to maintain a daily and complete action of the bowels. Calomel is the best purgative; from two to five grains at night, followed in the morning, if necessary, with a saline draught. This is the most important adjuvant to the action of salicylic acid, and I will presently explain to you why this is the case.

Seventhly, let the patient be enveloped in a light blanket, and with no more bedclothes than are sufficient to keep him from feeling cold. The object of the treatment now is to cool the patient—not, as in former times, to sweat the poison out of him; and the cooler he is kept, the sooner will the temperature be lowered. In fever, increased heat increases the metabolism, just as in a cold-blooded animal.

THE RECENT MEETING AT ST. LOUIS.

The proceedings of the recent meeting of the American Medical Association reveal two facts which are worthy of special notice—one of omission and one of commission.

When the Code of the Association, its "palladium of honor," was assaulted in New York, there arose in its defence, in the Empire State, a central figure. When its ambiguous clauses needed a more definite interpretation than they had heretofore received, and the whole instrument trembled in its very foundation, this captain stepped into the breach and wrote with the hand of a master. In the planning and preparation for battles the strong arm of his counsel could always be traced, and in the thickest of the contest his bright plume could always be seen. He chased the mists of doubt away from his followers, and waged a vigorous and relentless warfare. His presence always lent inspiration, and his acknowledged wisdom and influence gave him the power of a general. For his loyalty and his labor he was rewarded with the highest professional honor within the bestowal of his *confrères*.

So recently has this faithful servant and ornament to the Association passed away that we can hear the rustle of the priestly robe around his bier, and yet—and yet *the hallowed memory of Austin Flint passed unnoticed*, save by the address of the President, whose official obligation demanded the recognition of the annual death list of his predecessors in office. For this body, then, his memory has been like a snowflake upon the sea, "a moment seen, then lost forever." Sad commentary on the life of a faithful and honored public servant.

When the Judicial Council re-opened the case of the Philadelphia County Medical Society it committed an essential error, one which has sacrificed its exalted position, and which will lend color to the statement that it has descended from the dignity of a high court of law to the low level of politics. It, being a body which makes its own rules of action, may have had the power exercised, but a decision having been made, written out, officially signed, and laid upon the table of either the President or Secretary—where by custom, if not by rule, it was entitled to take precedence of all other business—it should have remained the decision of the Council. If the evidence was incomplete the Council should not have rendered its decision. The fact that it handed down a decision must be accepted as evidence that the Council had heard the evidence, and had closed the case. From its decisions there is no appeal, and in this respect the Council is not unlike the Supreme Court of the United States. As well might this Court, after hearing the arguments in a case and handing down its decision, at once recall, rehear, and redecide the same, reversing its own decision, as for the Judicial Council to have pursued the illogical course it did. The plea in extenuation, that new evidence was offered, is invalid, and savors strongly of the methods of politics.

SOME EXPERIENCES IN THE TREATMENT OF DIPHTHERIA.

During six years Dr. P. Werner, of Narva, Russia, treated ninety cases of diphtheria. The death-rate ranged from sixty to seventy per cent. This high mortality, however, affected only the first seventy-three cases. Among the last seventeen only two died, and as these were moribund when Dr. Werner was called in, he thinks that he can say that practically he had no mortality in his last cases. This remarkable fall in the death-rate he attributes to a change of treatment. His treatment, as thus very wisely changed, consisted in giving corrosive sublimate internally, and rubbing ichthyol upon the swollen glands, together with the use of "milk and again milk," but no alcohol. He gave to a child one and a half year of age a mixture of one-fourth grain of sublimate in four ounces of water. This was administered every one-third or one-half hour, so that the child took the whole in twenty-four hours.

Dr. Paul Hesse has been using bromine in diphtheria, and thinks that, while it is no specific, yet in experienced hands it is a most useful agent, exceeding, in fact, all others. Hesse at first applied bromine locally every one to three hours, using the following solution:

℞. Bromin.,
Potas. bromid.....āā 0.5
Aquæ..... 200.00
M.

This solution he also dropped upon the sponge of an inhaler, and had it used in this way for five minutes every half hour. He finally gave up the local application and used only the inhalation, modifying the strength of the dose according to the severity of the case.

For the swelling of the glands of the neck, he used an "ice-cravat." Hesse's conclusions, based upon one hundred and fifty cases, are that bromine is the best agent for the local process in the throat. Early tracheotomy is the best thing against laryngeal diphtheria, and a stimulating treatment is the best thing for the general condition. These three things make up the treatment *par excellence* of diphtheria.

Dr. C. G. Rothe, of Alenburg, has for some time advocated the administration in diphtheria of cyanide of mercury, and he claims to have had under its use a mortality of from three to five per cent. only. Since April, 1885, Dr. Rothe has given the biniodide of mercury in place of the cyanide, using the following solution:

℞.	Hydrarg. biniodid.....	0.012
	Potas. iodid.....	0.20–30
	Aquæ dest.....	60.00
	Tr. aconit.....	1.00

M.

Of this, one teaspoonful was given hourly to children under three years of age, and more proportionally to older persons. Rothe claims that he treated forty cases in this way without a single death.

A very severe case of diphtheria was treated successfully by Dr. Richmond, of Greenwich (*Lancet*), by pencilling the throat with iodoform, and giving the same drug by inhalation. A study of the above contributions shows again how far apart the profession still is as regards the treatment of diphtheria, and how very much concerted effort in the study of its therapeutics is needed.

THE BACILLUS OF RHEUMATIC PERICARDITIS.

In June, 1885, Dr. Albert Wilson, of Leytonstone, Scotland, reported the discovery of a "micro-bacillus" in the exudation in a case of fatal pericarditis.

In the *Edinburgh Medical Journal* for April, 1886, Dr. Wilson reports a second case, and again describes the bacilli which were present.

The patient was a boy, twelve years of age, who had some rheumatic symptoms, culminating in a pericarditis from which he died. On autopsy the pericardial cavity was found filled with a sero-fibrinous effusion, and this, when examined under the microscope, showed short, non-nucleated bacilli, but no micrococci.

Dr. Wilson made some careful cultivation-experiments in flasks containing sterilized broth, and he found that the bacilli grew, developing nuclei at each end, and forming long threads of jointed bacilli.

Some interesting experiments were made to determine the relative power of salicylate of sodium and of quinine sulph. in checking the growth of this organism. It was found that while a two per cent. solution of quinine would entirely check its growth, it required a five per cent. solution of the salicylate.

This, Dr. Wilson thought, was in accordance with his experience, that while in rheumatism and rheumatic endocarditis the salicylates are most effectual, yet in pericarditis quinine did more good. This seems to us rather fanciful; but Dr. Wilson undoubtedly has seen and cultivated a bacillus which is to be found sometimes, if not always, in pericarditis. If it is the cause of the disease, and a two per cent. solution of quinine kills it, then it would seem as if the rational treatment of pericarditis is to wash out the pericardial cavity with the solution in question.

FOREIGN MEDICAL DELEGATES AND THE INTERNATIONAL MEDICAL CONGRESS.

Many, indeed, most of our foreign brethren, are in a state of mind as to what all the quarrel over the next International Congress means. And while in this condition of doubt and ignorance as to whether there is to be an International Medical Congress, or only a National Domestic Quarrel, they naturally do not care to plan for a trip here next year.

To these gentlemen we would say: We have had in this country certain disputes, mainly over the question whether the Congress organization should be controlled by the American Medical Association, a society of about three thousand members, or by the medical profession of sixty thousand men. In this dispute the American Medical Association has conquered, but by methods which have caused the resignation and withdrawal of the great majority of the American physicians best known abroad and at home. There will be an International Medical Congress, but, according to the present outlook, a Congress in which many of America's best physicians will be absent.

Still, we say to foreign delegates, You will meet a large number of able and hospitable gentlemen at the Congress, you will be made warmly welcome by all Americans, and you will hear no quarrelling while you are in the States. We know that many medical gentlemen in New York, Philadelphia, Boston, and other medical centres, debarred from receiving guests in an official capacity, will be glad to welcome all foreign visitors unofficially and pay them every hospitable attention.

THE ASSOCIATION AND THE CONGRESS.

The action of the American Medical Association in continuing the policy and organization of the Executive Committee of the International Medical Congress only fulfilled the general expectation. If the act had been done in a less arbitrary manner, without first excluding all persons likely to bring up any discussion or opposition, a general effort at co-operation might have been secured.

But the organization and management are definitely settled, and we have no desire now to hamper its future work. We do not think that hereafter the International Medical Congress will meet with any aggressive opposition or criticism. Its managers have chosen their course, and we shall be glad, for the sake of our country's reputation, to see them successful in it.

But how can it be denied that the medical profession of this country is now very imperfectly represented in the organization of the Congress? And how can fair-minded persons help feeling that it is a serious mistake for the men who now are connected with it to go before the world as representatives of the best of the medical profession of the United States.

A PERMANENT SPLIT IN THE AMERICAN MEDICAL ASSOCIATION.

Now that the American Medical Association has finished its session, and its members have dispersed to their homes, there must come to all a period of calm reflection. Such reflection can hardly fail to show that the Association has committed another serious error, and one from which it will not soon recover. We refer to the arbitrary refusal to admit the Philadelphia delegation. This delegation was the only one sent by the Philadelphia County Medical Society, it was duly accredited, and its rejection was a piece of injustice and folly so monumental as to make one wonder if the gods had not infused some mad frenzy into the minds of the Judicial Council. The immediate result of this act will be to alienate the profession of Philadelphia from the Association, and the sympathies of a very large majority of the profession not attached by political ties to the Association will go with them.

For it is again demonstrated that the American Medical Association has fallen into the hands of political managers whose unskilfulness and stupidity are so astounding that we feel inclined to commiserate more than condemn.

No doubt the American Medical Association believes that it can get along quite well enough without the co-operation of the leading physicians of Philadelphia, New York, Boston, and Baltimore, etc., but without them it can no longer call itself a national or representative body.

The American Medical Association will continue to live, and we trust will thrive, but it is permanently divided, and will, we fear, never again represent the whole American profession.

News of the Week.

MEDICAL DEPARTMENT, UNIVERSITY OF NEW YORK.—Dr. Wesley M. Carpenter, of this city, has been appointed Clinical Lecturer on the Practice of Medicine in the Medical Department of the New York University. This is an honor peculiarly well deserved.

DR. GEORGE H. ROHE'S name, as Chairman of the Section on State Medicine, was omitted accidentally in our report of the proceedings of the American Medical Association.

INTUBATION OF THE LARYNX.—Dr. O'Dwyer described his new process of intubation of the larynx at the New York Post-Graduate Medical School and Hospital on Friday, May 7th, before the students of the College and physicians of the city interested in this subject. Tubes of various shapes and calibre were shown, and the operation was demonstrated on the cadaver.

ANOTHER OF THE WOLF-BITTEN PATIENTS of Pasteur is dead of rabies, according to *Le Progrès Médical* of May 1st.

CHOLERA IN ITALY.—A considerable number of cases of cholera occur daily in various parts of Southern Italy. At Brindisi four or five new cases are reported daily.

STATISTICS OF M. PASTEUR'S HYDROPHOBIA PRACTICE.—At a recent meeting of the Academy of Sciences, Paris, M Pasteur announced that he had treated the following number of people from different countries for bites from mad dogs: France, 505; Algeria, 40; Russia, 75; England, 25; Italy, 24; Austro-Hungary, 13; Belgium, 10; North America, 9; Finland, 6; Germany, 5; Portugal, 5; Spain, 4; Greece, 3; Switzerland, 1; Brazil, 1. This makes a total of 726.

PASTEUR'S METHOD COMMENDED.—Dr. von Frisch, who was lately sent to Paris by a Vienna committee to inquire into Pasteur's system of inoculation against rabies, has given an account of his researches in a public meeting at the Town Hall. He unreservedly commended Pasteur's system, urging that it should at once be adopted by the medical profession in Austria. Giving some statistics on hydrophobia, he said that in Austria there had been 135 deaths from this cause in 1874, and 132 in 1875. In 1882 the mortality declined to 77, the lowest figure on record.

THE PICTORIAL SPIRIT OF THE AMERICAN MEDICAL ASSOCIATION.—One of the curious features of the last Association meeting was the way in which it was hippodromed by the daily press. The columns of the papers were filled with all kinds of gossip, biographical and personal notes, jocose comment, etc. To cap it all, there were issued each day some eight or ten pictures of those members supposed by the reporters to be leaders in medical science, or especially distinguished for personal loveliness. The list of the representative men of the Association pictorially presented is interesting. Naturally, St. Louis leads in number, not because she has the handsomest doctors, necessarily, but her geographical position at the time, no doubt, gave her an extra hold upon the artist reporters. Chicago follows close behind, and we are glad to note that Dr. Davis has the largest picture of all, being very near a three-quarters length. Philadelphia is represented by one L. D. Gross (?) and Dr. Atkinson. The classic features of the Association Secretary cannot be made unattractive even by a St. Louis woodcut. New York and Boston were, unhappily, not represented, but Jerseyville, Ill., and Bloomington of the same State have each an unusually handsome doctor. The great State of Texas, which produces annually millions of bales of cotton, or some other equally valuable product, had only one pictorial representative—an injustice which we trust will be properly commented upon by our fiery contemporary of Austin.

DR. JAMES S. MCKENZIE, of Baltimore, died on May 10th, aged sixty-seven.

AN ENGLISH CONTEMPORARY refers with some dismay to our figures showing the output of medical graduates in Chicago, and in some strange way credits us with speaking of this prolific production of doctors as "a service to the profession." We have not so regarded it. But contemporaneously with our announcing an annual output from Chicago of 285 regular and 215 irregular medical graduates, our esteemed contemporary, Dr. N. S. Davis, was congratulating Chicago upon its evidences of being a great medical centre. Hence, perhaps, some confusion.

A Testimonial to Professor von Troeltsch.—In recognition of the great labors for the advancement and development of the science of otology by that eminent surgeon, Professor von Troeltsch, his admirers in the profession have presented him with an address, accompanied by an album, containing the photographs with signatures of most of the eminent otologists of the present day. The address is a tribute to the energy and genius of the master, who, for more than a quarter of a century, has devoted himself to the scientific and practical development of otology. It testifies to his vast services in the study of the anatomy and pathology of the ear, and furthermore to our indebtedness to him for the introduction of many new methods of examination. His energy, directed toward the liberation of otology from the narrow bonds of specialism, and exerted for its equal recognition with the other sciences, by the state, as an object of instruction at the universities, is highly praised. The writings of von Troeltsch are ornaments of medical literature, distinguished by their clearness and descriptive power. The address concludes with the hope that the master may long be spared to his family, friends, and admirers, an adornment to the university, a noble example of scientific attainments. Among the many well-known names of otologists, of all countries, accompanying the address, are those of Sexton, Seely, Prout, A. H. Buck, and Orne Green, representing the profession in this country.

The Utility of Spaying.—We note with pain that our article upon the utility of spaying has been misunderstood by our intelligent contemporary *The Alienist and Neurologist*. We are credited with being serious champions of spaying until thirty-five per cent. of all womankind have had their ovaries removed. Our views with regard to unnecessary gynecological interference have always been so pronounced that we did not think it possible our article could be misunderstood. We fear that our St. Louis contemporary is not a "constant reader."

Homœopaths as Readers of Scientific Medical Works.—A prominent publisher of regular medical works has said that he sold more books, proportionately, to homœopaths than to regular physicians.

The Practice first established in medical journalism by The Medical Record, of printing a daily edition during the session of the American Medical Association, was adopted by our enterprising contemporary, *The Weekly Medical Review*, at St. Louis, last week.

The Medical Society of the State of Florida meets at Palatka on May 18th.

The Imperial University of Japan has been reorganized. One of its most important departments is the College of Medicine. This is presided over by Dr. Miyake, a physician of wide reputation and extensive learning. The main course of instruction is modelled after that in the German medical colleges; the foreign professors, of whom there are at present five, are also German. The course covers a period of four years, and the preparatory course three years more. There is also a course of lectures delivered in the vernacular, which is called the special course. The total number of students last year was nine hundred and seventy-two. The Medical School of Japan is eleven hundred years old. In its early days it was presided over by a superintendent and assistant, under whom there was one medical professor, one professor of acupuncture, one professor of massage, one professor of diseases of women, a teacher of materia medica, botanists, and a number of physicians. The whole course covered seven years.

The Sei I Kwai Medical Journal.—We are glad to learn that our esteemed Japanese contemporary is prospering, and is able to enlarge its valuable columns.

The Medical Department of the University of Pennsylvania.—Dr. E. T. Reichert has been elected Professor of Physiology, vice Dr. Harrison Allen, resigned. At the annual commencement, held May 1st, a class of one hundred and eighteen was graduated.

The American Laryngological Association meets in Philadelphia on May 27th, 28th, and 29th, under the presidency of Dr. Harrison Allen. A list of twenty-three papers, to be presented by as many members, is given in the programme; with a banquet on the 28th, and an excursion on the 29th.

American Medical Editors' Association.—The annual address before this Association was delivered by Dr. H. O. Walker, of Detroit. The officers elected for the next year are Drs. J. V. Shoemaker, of Philadelphia, President; Dudley S. Reynolds, of Louisville, Vice-President; William Porter, of St. Louis, Secretary. Ex-President Walker was empowered to appoint a committee to invite the editors of the Old World to attend the next meeting. The banquet given by the Medical Press and Library Association, at the St. Louis Club House, was an elegant affair. The toasts were numerous, the responses brilliant, and the attendance large.

A Maternity Hospital has been organized in Buffalo.

Another Endowed Medical College.—If we are correctly informed, the Medical Department of Eulane University of Louisiana (formerly the Medical Department of the University of Louisiana) is to be classed with the medical schools having a very substantial endowment. Aside from property valued at $80,500, the college gets its share of an annual income of over seventy-five thousand dollars (Report Commissioner of Education, 1884). Surely, with such resources, the New Orleans college ought to do better than simply require the old low standards for graduation, with no preliminary requirements whatever.

The Fifty-five Million Population of the United States have 89 regular medical colleges, with about 10,000 medical students; 8 of these medical colleges have each from 300 to 600 students, and 7 of these colleges have from 200 to 300 students.

The Missouri State Medical Association.—This Association held its annual meeting at St. Louis on May 3d. In the absence of Dr. Catlett, Drs. C. A. Todd and J. W. Jackson presided. A motion to have the Society meet at one place every year was lost. A number of scientific papers were read by title, and referred to the Committee on Publication. The Treasurer announced that the Society had a balance of $450 in the treasury. A resolution from the Woman's Temprance Union, re-

commending the teaching of the physiology with regard to tobacco and alcohol in the public schools, was not adopted. Dr. Griffiths, of the State Board of Health, read a communication setting forth the work of the Board, and calling attention to some points with reference to which it was of importance that the profession of the State should co-operate with the Board. The Association then elected the following officers for the ensuing year: J. W. Jackson, Kansas City, President; J.W. Moss, Columbia, First Vice-President; W. E. Fishel, St. Louis, Second Vice-President; C. L. Lamb, Hannibal, Third Vice-President; Linsley Brown, Hamilton, Fourth Vice-President; J. S. Gillette, Rich Hill, Fifth Vice-President; J. C. Mulhall, St. Louis, and E. Cave, Mexico, Recording Secretaries; R. F. Brookes, Carthage, Corresponding Secretary; J. H. Thompson, Jefferson City, Treasurer. The Society adjourned to meet next year at Macon City.

Boycotting a Professor.—The medical students of the University of Vermont, on May 10th, organized an open protest against their recently appointed Professor of Surgery. They refused to attend his opening lecture, and marched around town making a demonstration during the lecture-hour. The trustees elected Dr. Bingham to the chair made vacant by the death of Professor James L. Little. The students made a written protest against the appointment of Dr. Bingham, on the ground that he was not a man of sufficient experience, and that he had made serious mistakes in diagnoses and operations in clinics before the class. The trustees made an informa investigation, but did not alter their decision. The students thereupon voted to boycott the new professor. The students are doing a serious injustice to a gentleman of excellent surgical skill and reputation.

Typhus Fever in a Children's Asylum.—Five children from the Deborah Nursery, a Hebrew asylum of this city, and one from the branch at 95 East Broadway, are in Riverside Hospital with typhus fever. They caught it from Otto Schultz, who was hired by the nursery at Castle Garden a fortnight ago as porter. There are nearly one hundred children in each branch of the nursery, and more cases are expected.

The American Climatological Association held a very successful meeting during the past week in Philadelphia. Members were in attendance from New York, Baltimore, Michigan, Boston, Georgia, and other places. A resolution was adopted appointing a committee on the organization of a Congress of Physicians and Surgeons of the United States, this committee to confer with that of the American Surgical Association.

Female Medical Students in a Massachusetts Hospital.—It is reported from Boston that the surgeons and medical students in the operating room of the City Hospital were given a shock last week while a male patient was being treated for some genito-urinary disorder by the appearance of a bevy of female students from a local medical school, under the lead of one of their instructors. All took seats with the evident intention of viewing the operation. They were at once requested to withdraw, but refused to do so. The surgeon in charge then informed them that unless they withdrew he would not perform the operation, but this had no more effect than the previous request to withdraw. They still held their seats. Accordingly, operations were transferred to a private room, and they were left in the possession of the place, where they remained for some time. A fortnight ago a similar attempt was made by female students, with two of their instructors, to attend an operation here.

The Censorship of Members of the New York Academy of Medicine.—The New York correspondent of the *Journal of the American Medical Association* reiterates his statements that the New York Academy of Medicine has no machinery for expelling dishonorable members, and circulates the following story: "A Fellow of the Academy having done some action (which need not be mentioned here) believed to be worthy of censure, a member of the Council, a gentleman of refinement and great eminence in the profession, was asked to remonstrate with him in regard to the supposed offence; but when the latter attempted to do this, on more than one occasion, if the writer is correctly informed, he was coolly greeted with the polite advice to 'go to h—ll.' Now, what can the Academy do about it? In former times the course to be pursued would have been sufficiently plain, and there would have been no hesitation in taking suitable action." It would be interesting to know whether the correspondent is "correctly informed," he himself appearing to have some doubt. Certainly this is an unsavory and unauthenticated story. We hardly see how its relation can interest the readers of the *Journal* or benefit anybody.

The Illinois State Medical Society meets at Bloomington on the third Tuesday in May.

Recent Operations in Brain Surgery.—A few months ago a man was admitted into the Middlesex Hospital, under Dr. Cayley, suffering from coma, which had supervened upon a long-standing purulent discharge from the ear. There were no localizing symptoms. Mr Hulke trephined the skull in the lower part of the temporal fossa, and by means of a director explored the temporo-sphenoidal lobe, without result. The operation was unattended with ill results, but after the patient's death, a few days later, an abscess was found in the cerebellum. Quite recently a woman was under Dr. Cayley's care with similar history and symptoms, and intra-cranial suppuration was diagnosed. Mr. Hulke determined to explore the brain. In this instance he made an aperture in the cerebellar fossa of the occipital bone, and through a small incision in the dura mater he passed a director through the cerebellum in all directions, but without striking an abscess. Finding that the symptoms were unrelieved, he subsequently trephined the temporal fossa and opened an abscess in the temporo-sphenoidal lobe We believe these cases will be duly reported to one of the medical societies.

A very Broad Hint.—A physician in this city is said to have the following inscription on his bill-heads: "A patient's gratitude to his doctor is a part of his disease, and is most declared when the fever is highest, cools off during convalescence, and entirely disappears with the complete return of health. All bills due upon presentation. Office prescriptions and attendance strictly cash."

Reviews and Notices.

THE DISORDERS OF MENSTRUATION. A Practical Treatise by JOHN N. UPSHUR, M.D., Professor of Materia Medica and Therapeutics in the Medical College of Virginia, Richmond, Va. New York and London: G. P. Putnam's Sons. 1886.

THIS little book is modestly called a student's manual, and a very practical and useful instructor it is for students. But it is not the student alone who may derive benefit from reading it, for it contains many valuable hints which will be of service to no small number of practising physicians when worried by a perplexing case of this nature. The work is divided into ten chapters, treating severally of amenorrhœa, menorrhagia, dysmenorrhœa, the neuroses of menstruation, pelvic cellulitis, vesical irritation, etc. It is written in a pleasant style, and the histories of illustrative cases are introduced wherever necessary.

HAWES' PHYSICIAN'S RECORD. M. E. Hawes, East Weymouth, Mass.

THIS is a simple pocket memorandum for daily records. Each page is so arranged as to record for one month a patient's pulse, temperature, general condition, etc. It is compact and attractively arranged.

ESSENTIALS OF PHYSICS AND CHEMISTRY. By CONDICT W. CUTLER, M.D., Physician to New York Dispensary. New York: J. H. Vail & Co. 1886.

THIS small pocket manual has been prepared principally for examination reviews. Its merits are completeness and simplicity. It is one of the best works of the kind we have seen. The subject of organic chemistry, generally difficult for medical students, is plainly set forth.

DOGS IN HEALTH AND DISEASE. By JOHN SUTCLIFFE HURNDALL, R.C.V.S. Pp. 88. London: E. Gould & Son. 1886.

THIS seems to be a very complete, yet condensed, account of canine diseases. The author gets somewhat off the track in his "humble attempt to elucidate the great truths of homœopathy," and in his advice to buy remedies only of homœopathic druggists, etc. Twaddle similar to the foregoing occupies about one-fourth of the volume. The remainder seems to be fairly sensible.

A MANUAL OF ANIMAL VACCINATION. By DR. E. WARLOMONT, Member Royal Academy of Belgium, etc. Translated by Arthur J. Harries, M.D. 16mo, pp. 168. London: J. & A. Churchill. 1885.

THIS volume opens with some general observations on vaccination. The various methods of inoculation are discussed seriatim, and their relative advantages and disadvantages set forth. The author, while admitting the possibility of syphilitic inoculation, does not believe that any other disease is so transmitted. One valuable part is a bibliography of the chief works upon the subject.

UEBER ACETONURIE UND DIACETURIE. By Von DR. RUDOLF VON JAKSCH. Pp. 156. Mit sechs Holzschnitten. Berlin: Verlag von August Hirschwald. 1885.

THIS monograph by Jaksch furnishes a very complete and exhaustive description of acetone and diacetone, in all their chemical and pathological relations. It is quite an indispensable contribution for the student of the interesting and much mooted subject of acetonuria.

THE INSANE IN THE UNITED STATES AND CANADA. By D. HACK TUKE, M.D., LL.D. Pp. 265. London: H. K. Lewis. 1885.

NO English or foreign alienist has taken the intelligent interest in the care of the insane of the United States shown by Dr. Tuke, and we are certainly indebted greatly to his candid and unprejudiced criticisms. The present volume is a critical summary of the methods of caring for the insane in a large number of American and Canadian hospitals, and it contains, besides, a considerable collection of statistical matter with regard to the condition of the insane, and insane asylums. Dr. Tuke opens his work with a most appreciative and interesting chapter upon Dr. Benjamin Rush, whose writings and practice show him to have had some of the same spirit that actuated Pinel, Conolly, and the Superintendents of the York Retreat. Dr. Tuke is severe in his criticisms of certain Canadian institutions; he also recognizes the evil results which politics and legislative parsimony have brought about in the care of the American insane. The potent influence of Dr. Gray was not strong enough to prevent a strong condemnation of the Utica crib, of which he says he found fifty in active use in one asylum. Dr. Tuke's book will be found an extremely useful one for persons desiring a lucid and unbiassed account of the condition of our lunacy laws and of our insane, more especially in the North and East.

WEITERE UNTERSUCHUNGEN UEBER PTOMAINE. Von PROFESSOR L. BRIEGER. Pp. 83. Berlin: Verlag von August Hirschwald. 1885.

PROFESSOR BRIEGER'S monograph gives an interesting historical account of the ptomaines, and also describes his researches with bacteria. He shows that the growth of certain pathogenic micro-organisms is accompanied with the evolution of certain ptomaines.

PROCEEDINGS OF THE NEBRASKA STATE MEDICAL SOCIETY. Seventeenth Annual Session. Held at Grand Island, May 26–28, 1885. Lincoln: State Journal Co. 1885.

THE report of the proceedings of the seventeenth annual meeting of this flourishing Society makes a handsome volume of upward of four hundred pages. The usual number of papers—some interesting, others not—were read, and the usual protest against the action of the New York State Medical Society upon the Code question (rather ancient history, by the way) was indulged in. The meeting was a decided success, and the papers, taken as a whole, reflect credit upon the physicians of Nebraska.

COCA, COCAINE, AND ITS SALTS. Their History, Medical and Economic Uses, and Medicinal Preparations. By WILLIAM MARTINDALE, F.C.S., late Examiner of the Pharmaceutical Society, and late Teacher of Pharmacy and Demonstrator of Materia Medica at University College; Joint Author of the "Extra Pharmacopœia." London: H. K. Lewis. 1886.

THIS is a little book of seventy pages printed in blue ink on green paper, a combination of colors which the author says is admirable for the sight, but which, perhaps because of its novelty, is not especially pleasing. The description given of coca and its alkaloid, and their uses in medicine, is admirable, and we can recommend the brochure as an excellent supplement to any of the standard works on materia medica written before the introduction of this most valuable drug into general use in medicine and surgery.

THIRD ANNUAL REPORT OF THE BUREAU OF STATISTICS OF LABOR OF THE STATE OF NEW YORK FOR THE YEAR 1885. By CHARLES F. PECK, Commissioner.

THIS is an exhaustive report on labor problems of the present. Separate chapters are devoted to strikes, boycotting, and arbitration. The scope of the Commissioner's work has included inquiries into the sanitary condition, etc., of factories, and that of the homes of the working classes. No essentially new information is adduced, but a salutary effect must follow this official examination of the subject. The officials of our New York City Health Board are taken severely to task for the filthy condition of certain parts of the city, but as long as this body is managed by politicians the chances for any improvement seem poor indeed.

Reports of Societies.

American Medical Association.

Thirty-seventh Annual Meeting, held in St. Louis, Mo., May 4, 5, 6, and 7, 1886.

SECTION IN OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

WEDNESDAY, MAY 5TH—SECOND DAY.

DR. H. O. MARCY, of Boston, exhibited on the screen a number of cuts in treating of

THE LESIONS OF THE PERINEUM AND THEIR REPAIR.

These consisted of frozen sections, among others that of a woman who hung herself in the eighth week of pregnancy; another who died during parturition. He showed the bladder and rectum full and empty; the dissection and repair in operations on the perenium; showed Emmet's operation, complimenting his method of dissection; cuts from Hart, Henly, and Savage, and showed cuts of his own manner of operating, which he had reported to this Section two years ago. He also showed his "safety-pin," made of heavy German-silver wire.

DR. GEHRUNG, of St. Louis, presented sutures of his own.

DR. S. C. GORDON, of Portland, Me., said that for eighteen months he had used nothing but

CATGUT SUTURES IN PERINEAL OPERATIONS,

with the exception of the complete rupture. He makes the crescentic denudation; never has any trouble, pain, or discomfort, as there are no stitches to remove.

DR. WATHEN, of Louisville, Ky., in speaking of Dr. Gehrung's sutures, said they had some benefits, but they were more than overcome by the presence of the bodies on each side. He thought it best to use the suture which caused the least pain and perfectly adapted the parts. In incomplete laceration of the perineum a failure is the exception to persons of experience. The operation described by Dr. Marcy has value superior to the operation of Emmet. He thought that Dr. Marcy's needles would cause some pain by their mere presence. The advantage of Dr. Marcy's operation is that we do not destroy any tissue. Destroy no tissue, get perfect adaptation and union, and no septic matter can get in. He destroyed no tissue in a complete or incomplete rupture. Two great improvements are the manner of denudation and the saving of tissue by Dr. Marcy.

DR. GILLESPIE, of Tennessee, thought the time of operation of importance; after three days' delay he has had unusually good results. He prefers Emmet's plan, with the silver sutures and the straight, round needles.

DR. MARCY in reply said there was no amount of inconvenience or suffering from the pins if they are placed parallel and do not compress the tissues. He spoke of and showed sutures made from the tail of the fox, squirrel, and the kangaroo.

DR. E. W. CUSHING, of Boston, showed a number of microscopical specimens on the screen in discussing

THE PATHOLOGY OF EROSIONS, SO CALLED, OF THE OS UTERI.

DR. A. C. MILLER, of Cleveland, O., discussed the paper, and was replied to by Dr. Cushing.

DR. W. W. POTTER, of Buffalo, N. Y., read a paper entitled

SOME OBSERVATIONS ON THE UTERINE SOUND, WITH ESPECIAL REFERENCE TO ITS USE IN GYNECOLOGICAL THERAPEUTICS.

It was but a few years ago when a Ferguson's speculum, caustic-holder, uterine dressing-forceps, and Simpson's sound were an ample outfit for the practice of gynecology. The sound has been used in almost every malady peculiar to the pelvic organs, and I am sure it is in the range of truth to assert that this instrument has done woman more harm than any other used in the management of her diseases. The young physician is prone to its improper use, and, sad to say, causes often irreparable damage to the genital tract or health of woman. Nor is this animadversion applicable exclusively and alone to the professional novitiate, for many whose experience should have taught them better are guilty of the same. I myself am not holier than thou, but take a full share of blame for past misuse. My experience has taught me in every instance, in those cases which seem to invite its use for diagnostic purposes, most earnestly to use it with the utmost caution, circumspection, and gentleness. I would most strenuously insist that this instrument should be applied to only as a *dernier ressort*, and in juncture with extreme doubt. Have we not repeatedly seen endometrium so sensitive as to spring into violent inflammation as a result of contact with the sound? Metritis, both peri- and para-salpingitis, ovaritis, pelvic cellulitis, et id omne, are among the results. What, pray, may all these lead to? Were it possible to group together in one table where woman has been caused to abort by the use of the sound, what would be the array? Those indescribable symptoms, remote and reflex in character, also sympathetic, which we call neuroses—hystero-neuroses if you please, that are difficult to locate but unbearable—neuralgias, headaches, backaches, etc., count up a picture of woe pitiable to think about. Mr. Lawson Tait has found that in his own practice, as experience increases, his use of the speculum and sound grows less and less. This comes from the increased *tactus eruditus*. He says, educate the fingertips. This were well, but few of us can reach the perfection of a Tait. However, the nearer we can come to attaining this, the better gynecologists we are and the less will we use the sound. The essayist said that the os uteri should always be patulous, and the endometrium free from disease before the sound is used.

When necessary, the delicate virgin-silver probe of Sims is better and safer than the Simpson sound. This should never be passed at the first interview. We should, if possible, avoid it until we are quite familiar with the topography and peculiarities of the sexual tract of our patient. We should wrap absorbent cotton about the instrument to serve as a cushion for the metal. He could not speak in too strong terms against the use of the sound to replace the retropoised uterus. He named this use of the instrument as barbarous practice, and recommended the intelligent and persistent use of manipulation and the genu-pectoral position. The sound has taught us some good things, chief among them being the better use of our fingers. He hoped that with the use of the better educated finger-tips the sound would grow less and less in demand and use, and we shall be rid of much of the opprobrium which the young and growing art, gynecology, is now compelled to suffer.

DR. GORDON, the president, in a neat speech complimented the paper very highly, and endorsed every word of it.

DR. GEORGE ENGELMAN, of St. Louis, arose to express his thanks to Dr. Potter for having expressed in words what the speaker had practised for years. He had quite a collection of sounds, but in the past three years had not used one of them. The finger is far more satisfactory and true. The sound is useless in the great majority of cases. We have used ergot, the applicator, and the sound to the great injury of women. We are progressing in gynecology by dispensing with these. He had even found it unnecessary to use the soft pliable sound wrapped with cotton. The finger must be used for diagnostic purposes far more frequently than it is. Injury from the sound is far greater than the benefit derived.

DR. C. R. REED, of Middleport, O., thought the pa-

per was too strong in its statements, as were also the statements of Dr. Engelman.

Dr. Eugene C. Gehrung, of St. Louis, agreed with the essayist, as far as the abuse of the instrument was concerned, that the sound should not be used for displacements. He had put himself on record two years ago in the *Archives of Gynecology*. He recommended manipulation. We all know that in certain fat persons manipulations cannot be made. The sound can be used if the gynecologist has the proper regard for life. The speculum is frequently so useless that one must pass his hand alongside of it to find what it is he sees.

Dr. A. C. Miller, of Cleveland, O., regarded this portion of the essay ridiculous. The man who has not the caution or the education to use the sound carefully should not use it at all. Who can take the measurement of the uterus, or differentiate between the uterine and cervical cavity, with the finger? The inflammation referred to by Dr. Potter was probably caused by septic matter carried in on the finger. If gonorrhœa or septic matter is in the vagina, it should be well cleaned out before the sound is passed.

Dr. E. S. McKee, of Cincinnati, read a paper, subject,

THE EARLY DIAGNOSIS OF PREGNANCY.

The author considered the opprobrium obstetrici our inability to make a prompt and positive diagnosis of early pregnancy. Reliable evidence is sadly deficient in the first months. This fact in mind, he turned his attention to the symptoms of the first trimestrium, particularly those of late discovery. First were considered those signs which might occur at the time of conception. A number were mentioned, but the only one thought to be of any value was the peculiarly voluptuous sensation and more general erethism experienced on fruitful intercourse. An enumeration of the symptoms of early pregnancy generally known was then made. What was true of the first of these, absence of menstruation, was true of them all, viz., there were numerous exceptions to any one of them, and the same condition might be produced by other causes. Hence very unreliable testimony.

Among the later signs was mentioned that of Jacquemier, the slate or purple color of the vagina. Anything which impedes the circulation may cause this appearance. Dr. Joseph Taber Johnson has made a good suggestion. He thinks the principle of the telephone could be used to hear, much earlier than usual, the feeble sounds of the fœtal circulation. Dr. S. C. Dumm thinks he can diagnose pregnancy as early as the fourth week by the odor of the vernix caseosa upon the examining finger. Dr. E. C. Gehrung was able to make the diagnosis by the fifth or sixth week by the sensation imparted on touching the ovum with the sound. This is rightly condemned as dangerous practice, while it may be simulated by a polypus or other foreign body in the uterine cavity, and in the early weeks the ovum is only attached to parts of the uterine walls, and the sound may glide by. Pinard and Didsbury have treated of a gingevitis which begins about the second month. Jorrisenne, basing his observations on the law formulated by Graves, that in hypertrophy of the heart the radial pulse remains the same, whatever the position of the body, maintained that instead of the usual variation of from 10 to 20 beats in the non-pregnant woman, the pulse of the impregnated remains the same. The essayist and others had investigated this symptom and found it quite unreliable. Dr. H. D. Fry thinks that a rise in temperature in the cervix to one degree or more above the temperature of the axilla is a strong presumptive evidence of impregnation, provided there is no local disease. The author had found this true, but had found the rise of temperature in the vagina to be of less value.

To Hegar, of Freiburg, we are indebted to the new sign of great promise which bears his name. This consists of an unusual resilience, compressibility, softness, bogginess, yielding, and thinning of the lower uterine segment, that is, the section immediately above the insertion of the ligamenta sacro-uterina. The shape assumed is that of a fan, balloon, or jug. The change is most apparent in the median line. According to Compes the examination should be made as follows: The thumb is introduced into the vagina until it reaches the cervix, and the index into the rectum until it reaches the ligamenta sacro-uterina; the other hand is placed over the abdomen immediately above the symphisis and pressed down toward the finger in the rectum. The rectal finger explores the cervix and the lower uterine segment in all its parts, and, lastly, the higher parts of the uterus. The examination is facilitated by pulling down the uterus with the volsella, and evacuating the bladder and rectum. The author thought this mode of examination thorough, yet repulsive to both patient and physician, as well as a difficult and hazardous procedure. He thought it quite possible in the majority of cases to make out all that is necessary with the finger in one of the culs-de-sac and the other hand externally. If this is not sufficient, it would be quite proper to make the examination as above described.

The bladder distended with urine and the uterus with menstrual blood may simulate Hegar's sign. These can be easily differentiated. Hyperplasia would show increased density. Subinvolution would increase the longitudinal as well as the transverse diameters. In marked retroversion a careful examination per rectum is often necessary to find the sign.

Dr. Reinl, formerly assistant to Hegar, says: "Among twenty-two cases, I missed this sign but twice, and found it earliest in the fifth week of pregnancy." Dr. Compes, present assistant to Hegar, has reported six cases. Dr. E. H. Grandin, of New York, reports eighteen cases, and says he can make the diagnosis prior to the eighth week by Hegar's sign alone. The author had a number of cases under observation, most of which had not yet had time to develop. One, a widow, acknowledged the opportunity, and believed herself pregnant. Repeated examination failed to find Hegar's sign, and she was assured that she was not pregnant. After thirteen weeks the menses returned, and were normal in amount and duration. The other was a young wife who, after a four months' absence from her husband, returned to him February 9th. She soon came under the author's care, and her case required a digital and specular examination two or three times per week. Three times in the sixth week Hegar's sign was made out. March 31st, forty-eight days after her return, she miscarried.

There remains to us, then, to again lament our inability, in many cases, to make a positive diagnosis of early pregnancy, to mourn the fallibility of many of the new and all of the old symptoms, to especially recommend the sign of Hegar, which until now has proven itself impregnable, and to plead for investigators in a field which should not be "barren or unfruitful."

Dr. Gustav Zinke, of Cincinnati, read a paper on

PUERPERAL FEVER AND THE EARLY EMPLOYMENT OF ANTISEPTIC VAGINAL INJECTIONS.

The essayist did not wish to bring before the Association puerperal fever in detail, but to consider the value and necessity of antiseptic or simply warm-water injections, as recommended for prophylactic purposes in normal cases of labor in private practice.

The doctor based his paper upon a case in his own practice, which runs, in brief, as follows:

Mrs. ———, twenty-six years of age, in the eighth month of pregnancy. She had been under the doctor's care for retroversio-uteri and old pelvic cellulitic deposits. The progress of gestation was normal until the end of the eighth (calendar) month, when she was delivered of a healthy child. The doctor, on being called, diagnosed threatened abortion, and gave codeia and chloral

hydrate—the former for the relief of pain, the latter to produce sleep. Delivery followed. The placenta came away spontaneously, and almost immediately after the cord was severed. The external genitalia were washed, the labor having been quite normal in course.

The case progressed nicely until the third day, when she had a chill, followed by a temperature of 106°, but scarcely any pain, and the lochia free and inoffensive. Two hours later she had another chill, and the temperature went up to 107.5°, and pain in the left inguinal region. Professor C. D. Palmer was called in consultation. It was feared that the high temperature was due to something in the uterine cavity, but this was not thought possible from the nature of the labor, and it was determined to await the action of quinia before washing out the uterine cavity. Carbolized warm-water injections and turpentine stupes were added. Temperature fell to 101°, then rose to 103°. Still slight tenderness in the hypogastric region and the lochia free from odor. Temperature reached 104.5°, when the uterine cavity was washed out with warm carbolized water, using the reflex uterine catheter. This was followed by some pain, but there was no decline in the temperature, neither was there a removal of anything suggestive of trouble in the uterine cavity. Later, under the use of tincture veratrum viridi and salicylate of soda with diet, the temperature fell.

Comparing the local manifestations with the range of temperature, the doctor became more and more convinced that the malady was not local in character. True, there were present physical signs of cellulitis, but they were not present at the beginning, indeed, this condition diminished, while the pulse and temperature continued high with distinct morning remission and evening exacerbation.

Was it typhoid or remittent fever? Diarrhœa, rose-spots, and stupor were absent. The husband then stated that about a month before her confinement she had complained of languor and chilliness. Was it, then, remittent? In all probability. My consultant did not concur with me. The seventeenth day after confinement the temperature was 99.5°, next day 101.4° and still rising. The next day, the doctor's orders not being followed, he retired from the case. She lingered along, part of the time under the care of a physician, but no record of the temperature being kept till the illness had reached two months in duration, when the patient recovered.

The questions which present themselves for consideration are:

1. Was this a case of puerperal septicæmia, remittent fever, or something else?

2. Could it have been avoided by the early use of antiseptic vaginal injections?

3. To what extent is the use of antiseptics, scientifically and practically, justifiable or necessary?

The essayist did not believe it to be septic, but if so, thought it did not enter through the parturient canal. Puerperal fever, he thought, should embrace those diseases only which occur during the puerperal state. He was satisfied that all cases of puerperal fever which find their inception in an external cause, through the obstetric channel, may, to some extent, be successfully mitigated or prevented by the early and frequent use of antiseptic vaginal injections. Scarlatina, measles, diphtheria, etc., find their way through other avenues, and often mislead the physician. Antiseptics in normal labor ought not to mean anything except ordinary cleanliness in every respect, the avoidance of frequent examinations and unnecessary aids, needless exposure in the support of the perineum, the tying of the cord, the delivery of the placenta, and the washing after labor.

Washing out the vagina immediately after normal labor he thought meddlesome midwifery, did no benefit, prevented nothing, and might do harm. In prolonged or instrumental delivery, if the hand has been introduced or if injuries have been sustained, vaginal injections are always, uterine injections rarely, indicated.

The doctor referred to a death after vaginal injections in normal labor in the practice of Dr. Cleveland, of Cincinnati, and to the writings of Drs. Lydston and Bartlett against the routine injection. He added further testimony by relating three cases which occurred in his own practice, in which ill effects were observed after vaginal injections most carefully performed. Out of nearly four hundred cases of labor attended by the essayist, the case reported was the only one which could be suspected of being puerperal fever.

THURSDAY, MAY 6TH—THIRD DAY.

DISCUSSION OF DR. ZINKE'S PAPER,

read day previous.

DR. CHARLES KNAPP, of Evansville, Ind., thought that from the action of quinia and the non-action of the intra-uterine injections the case was not of bacterial origin. He believed in antiseptic midwifery, because it was clean midwifery.

DR. SARGENT, of St. Louis, had very little use for intra-uterine injections.

DR. HUNTER, of Minneapolis, spoke

ADVERSELY TO INTRA-UTERINE INJECTIONS.

He had assisted in killing one woman by these injections, since which time he held great respect for the uterine cavity. He has had unfavorable results with 1 in 2,000 sublimate solution.

DR. C. R. REED, of Middleport, O., gave, in a few words, the history of cases which came under his observation recently.

DR. REAMY thought the especial point aimed at by the essayist was the objection to the routine vaginal injection. The speaker wished to enter his protest against the routine vaginal injection of even simple water or water and soap. He does not deny the germ theory of the origin of disease, and that physicians and nurses may carry the means of infection, but wished to be placed on record as opposed to the routine injection. If you have septicæmia, then employ your germicides. Are we to think the vagina a foul crater? In the vagina of the woman recently delivered we find, after slight lesions, granulations. The employment of vaginal injections of simple warm water has a tendency to arrest granulation and prepare the woman for disease. If a vaginal injection does any good, we must wash out every hour; it is mockery to wash out one, two, or three times a day. The attending physician, to have this done properly, must do it himself, which is impossible. The nurse may throw a stream into the uterine cavity, and the patient die from the shock. It is dangerous to make a routine practice of injecting the vagina even with water, not to say chemicals. He wished to be understood as not against the germ theory, and in favor of intra-uterine injections under proper conditions after septic symptoms.

DR. W. W. POTTER, of Buffalo, asked where Dr. Reamy drew the exact line of beginning of septicæmia; sometimes this line is plain, sometimes it is not. He believed in letting well enough alone. If he had a purely natural labor he did not inject, but if he had gone in there instrumentally or manually he used the injection, fearing trouble. For washing out the uterus he recommended Chamberlain's glass tube, and said we should go up higher to find a faulty condition of the vagina. Before long we will be cremating every woman who has borne a child—she is so foul.

DR. ZINKE said in reply that he had brought this subject before the Section to vindicate himself; we owe not all to our patients, but something to ourselves. He felt very indignant when people blamed him for being the cause of all the trouble.

DR. FRANKLIN H. MARTIN, of Chicago, read a paper on

ELECTROLYSIS IN GYNECOLOGY.

The author first spoke of the theory of action, then described what took place in the normal tissue and in the

pathological tissue, or in pathological tissue mixed with normal tissue? He mentioned the principal advocates of electrolysis, and enumerated the diseases in which it was beneficial, viz., varices, polypus, nævi, epilation, hydrocele, bronchocele, extra-uterine pregnancy, hernia, hemorrhoids, epithelioma, and uterine fibroid. He also related his experience with an extra-uterine fibroid. This trouble is reported cured by this means by numerous authors. He gave the particulars of the application of the remedy, spoke of the mixed galvanic and faradic method, and showed his manner of applying electrolysis.

Dr. Ely Vandewarker, of Syracuse, N. Y., complimented the paper, and gave brief expression of his experience. He reported a case of solid uterine outgrowth to which he applied electrolysis. The operation proved to be very painful; the patient groaned and writhed under the pain, though anæsthetized. After eight days he observed a rise in temperature, and an abscess followed. The tumor was reduced in size, but the woman was very ill and barely escaped death. Two other cases have submitted to an operation, but the results have been negative.

Dr. Robert Newman, of New York, took great interest in the subject. He recommended weak currents. Instead of twenty, thirty, or eighty cells, we should use two, three, four, five, or six cells. The object is absorption. The strong current does harm; the weak causes absorption. In gynecology electrolysis has a wide field. The one great thing is, we have a safe and sure remedy to save the woman suffering from extra-uterine pregnancy. Do not use needles, use electrodes. In cases of hardened tissues, electrolysis has done much good in my experience. In malignant growths and cancers it has done good, and been followed by failure in stricture of the urethra in females. In my hands it has never failed. I hope the gentlemen will not forget to use weak currents.

Dr. Hulbert, of St. Louis, said he was an electrical crank. He reported some remarkable cures. He said we should measure the dose, as in other remedies, and thought Dr. Vandewarker's failures due to not having measured his dose.

Dr. George Engelmann, of St. Louis, said Dr. Martin had only brought this subject before them in a scientific light. He only touched on the results to be attained. He was surprised at Dr. Vandewarker's and Dr. Newman's speaking so indefinitely of strong and weak currents. He had always insisted on using the galvanometer. Know your dose. Cases had been reported here where cures occurred only after forty-five sittings. If you will measure your electricity, you will cure your patient in five or six sittings of five minutes each. The kind of electricity used is quite as important as the number of cells. Give a sitting of five minutes, and a strength of forty, fifty, eighty, or one hundred milliampères, according to how much the patient can bear; it may cause slight pain at first, but should not after that. Avoid the peritoneum if possible, but if necessary pass it through. He uses one needle and a large plate, fourteen by sixteen inches. The cells are gradually added, until the galvanometer shows enough.

Dr. C. R. Reed, of Middleport, O., read a paper on

THE IMPERATIVE NECESSITY OF ABDOMINAL SECTION AS ILLUSTRATED BY AN UNUSUAL CASE OF OVARIOTOMY.

An ovariotomy to attract the attention of the profession at present must be unique and have some features of peculiar interest. The essayist reported a case showing the necessity of operation, and showing that the death of the patient would have been inevitable but for the abdominal section, which made the diagnosis at once clear and the treatment plain. The case suggested the following questions: 1. Was the ovarian cyst, with its attending adhesions to the descending colon, the cause of the obstruction of the bowels? 2. Would the exploring needle have made the diagnosis clear without abdominal section? 3. With the probability of the patient dying under the operation, would it have been better practice to have tapped with the trocar and deferred the removal of the tumor? 4. As has been shown by the large experience of Tait and others, that abdominal section and exploration is, under antiseptic treatment, attended with little or no mortality, is it not the imperative duty of physicians to open the abdomen in all cases of doubtful diagnosis, where general treatment has failed to relieve the symptoms? 5. In all cases of slight enlargement of the abdomen, attended with intestinal obstruction, as in this case, should the physician wait until symptoms of apparent dissolution occur before resorting to abdominal section, and should the operation be performed as a means of diagnosis only when the symptoms are urgent?

Dr. Crouse, of Iowa, reported a case which was not an ovarian tumor; he diagnosed unilocular ovarian cyst, operated and found encysted peritoneal dropsy, probably malignant in character.

Dr. Reed in reply said that he was called in consultation, did not see the woman three minutes before he operated, and asked the gentlemen to only put themselves in his place, and see if they would have done better.

Dr. W. H. Walthen, of Louisville, did not understand why the incision was enlarged from four to five inches; he thought four inches sufficiently long; it is necessary to make long incisions when a large, hard tumor is to be removed, or there are numerous adhesions. He failed to understand why the ligature was left to hang through into the lower angle of the uterus.

Dr. Van Emmon, of Kansas City, could not understand why—the woman being threatened with death, and having stercoraceous vomiting and enlarged abdomen—the case had not been diagnosed earlier; also, why he was not prepared in a laparotomy to make an ovariotomy, if found necessary. He did not understand why the woman, if not an opium-eater, was given half a grain of morphine sulphatis, hypodermatically, previous to anæsthesia; he did not know from the paper whether it was a mono- or a poly-cyst, in fact, whether or not it was an ovarian tumor at all.

Dr. Joseph Eastman, of Indianapolis, arose to take the part of the gentleman who had read the paper. It brings up the all-important question, What is the physician to do in such an emergency? Physicians in practice are not accustomed to going prepared for an ovariotomy. He did not agree with Dr. Walker that it was improper to leave the ligature hanging through the lower angle of the uterus. This was the way in which Dr. McDowell did in his first case.

Dr. Cushing, of Boston, supported the last speaker and the essayist. There is an old saying, "It is a good bridge which carries a man over." Dr. Reed's case recovered, and that is the main object in medicine. It was better to make the incision large enough than to tear the intestines in getting out the tumor. The gentleman had no trocar with him. Schroeder and Martin do not use the trocar. He thought it a worthless instrument, and only one more to keep clean.

Dr. F. T. Paine, of Galveston, Tex., gave a brief report of a remarkable case of congenital absence of the ostium vagina, and delivery by the anus. He was called in consultation by Dr. Sacks, of Galveston, and found a young married woman in labor with her first child; the most careful examination failed to find any trace of an ostium vagina or a cicatrix. The vagina was found to enter the rectum, and the menstrual flow had passed this way. The child was born per rectum. The patient had never known that she was not as other women, nor was her husband aware of it. They had been married a year, and had both enjoyed sexual intercourse.

Dr. W. P. King, of Sedalia, Mo, spoke on pelvic inflammation and accumulation; he spoke of the two classes of inflammation, septic and non-septic, and thought a fertile source of disease was the "hand grease." In

he physician's office this is put upon the finger or hand, nd the finger or hand passed into the vagina or uterus. The sound is dipped into it and passed into the uterus. The cotton-wrapped probe had better be put in the ubliimate solution. The proper point to open the abcess is in the lowest part, which is the vagina.

Dr. French, of Minneapolis, showed a simple device, n the shape of a retention catheter, made from a rubber ube and a pair of scissors. He had had an alarming emorrhage follow the use of a small knife. He objected o the insufflators in general use, because they drew in ome matter, which they held until next used, and then nrew in septic matter; he preferred the insufflator having valve like the ones used by the aurists.

Dr. Harvey, of Indianapolis, advised the use of the eroxide of hydrogen as an injection.

Dr. Potter, of Buffalo, thought the uterine sound the nost common cause of pelvic inflammation; prevention of accumulation was the treatment. He used no arterial edatives in inflammation. He believed, with Drs. King nd French, that the sooner and earlier you evacuate the better.

Dr. Haggard, of Nashville, Tenn., spoke on prophyactic treatment. The introduction of the sound not infrequently produces inflammation. If we are more guarded with its use we will have less inflammation. We use ntra-uterine medication too frequently.

Adjourned.

SECTION ON DISEASES OF CHILDREN.

Tuesday, May 4th—First Day.

Dr. W. D. Haggard, of Nashville, Chairman; W. B. Lawrence, of Batesville, Ark., Secretary.

Dr. J. M. Dunham, of Columbus, O., read a paper

ON DIPHTHERIA.

He believed it to be a purely asthenic disease with local manifestation in the throat.

In the discussion that followed, all supported the same view, except Dr. C. J. Lewis, of Chicago, who believes that the disease at first is purely local.

The Secretary read a paper sent by Dr. J. M. Toner, of Columbia, Tenn., on the

NON-IDENTITY OF MEMBRANOUS CROUP AND DIPHTHERIA.

Adjourned.

Wednesday, May 5th—Second Day.

Dr. Mary Harris Thompson, of Chicago, read a paper on

WHY DISEASES OF CHILDREN SHOULD BE MADE A STUDY BY THEMSELVES?

She said opium and alcohol should in all their forms be discarded as soon as safer remedies could be found, and she was confident it could be done if the subject was more thoroughly studied. The rules for physical diagnosis would not well apply to a child, because they were undeveloped, the child being small and fretful a correct examination could not be had. Adult remedies were not applicable to a child, even in reduced doses, and it was as important to save the life of a child as an adult.

The discussion was spirited, but the speakers were divided upon the necessity of using opium and alcohol as remedies. Some would not use either in any of their preparations, under any consideration, while a like number felt they could not practise intelligently without either drug in their preparations. Dr. Thompson, in closing, said the application of external heat would often answer the purpose of both drugs, which should be discontinued for moral reasons, if for no other.

THE FIFTH GERMAN CONGRESS FOR INTERNAL MEDICINE.

Held at Wiesbaden, April 14, 15, 16, and 17, 1886.

Professor Leyden, President, in the Chair.

Thursday, April 15th—Second Day.

The second session was called to order by Professor Jurgensen.

The subject selected for discussion was

DIABETES MELLITUS.

Its consideration was divided into two parts, the first of which was taken by Professor Stokvis, of Amsterdam. His paper was entitled

THE RELATION BETWEEN DIABETES MELLITUS WITH ALBUMINURIA AND NEPHRITIS.

While it is true, the speaker said, that diabetes is a well-established and often well-defined disease, in which certain parts of the central nervous system are more or less injured in their functions, all our knowledge of the nature of so complicated a disturbance of the organic functions of the body have so far been nothing more than theoretical speculation. Transitory glycosuria and permanent diabetes are vastly different, yet albuminuria may, and very often does, accompany both. Albuminuria complicating transitory glycosuria does not depend upon nephritis, but in diabetes the author had often seen albuminuria caused by true nephritis in its various forms, ending generally in atrophy and cirrhosis of the kidneys. Grape-sugar alone, or with other morbid products, is the cause of diabetic albuminuria and nephritis. The latter generally begins in Bowman's capsules and the glomeruli. Simple albuminuria does not make the case any worse; nephritis gives a more serious prognosis. Yet there are many cases on record in which the diabetic symptoms disappeared under the influence of nephritis, and the patients with cirrhotic kidneys lived for ten or fifteen years, remaining free from glycosuria. We observe, then, that the prognosis is not absolutely unfavorable when diabetes ends in renal disease, as the patient may live comparatively comfortable when he has exchanged his diabetic for a cirrhotic kidney. French authors maintain that cirrhosis of the liver, developing in the course of diabetes, may have a similarly benign influence for the time being. In managing such complications it is of first import to regulate and support the heart's action.

In

DIABETIC COMA

the author distinguished between the light and severe forms. The latter is the most frequent and sudden end of diabetes, unless acute phthisis develops, when the patient will die without showing any signs of coma diabeticum. He considered fatal diabetic coma to be a particular form of uræmia, caused by the accumulation of acetone and other morbid products in the circulation under the influence of complicating renal disease; or it might result from sudden and abundant production of acetone, etc., although renal disease were absent, coming on after unusual exertion—the fatigue of a long journey, an attack of indigestion, etc. In the lighter forms the treatment requires all our attention, and as to severe coma our measures must be prophylactic; we must try to prevent the attacks by careful supervision of our patients.

In the

TREATMENT OF DIABETES

the speaker followed Bouchardat and Cantani, prohibiting the carbo-hydrates absolutely, and he was pleased with the results so far obtained. He insists upon muscular exercise, by which alone the percentage of sugar can be greatly diminished, regulates all the other functions of the system, and counsels also moderation in eating and all other matters. Such general treatment is

particularly adapted to fat and gouty patients, when they show symptoms of diabetes.

PROFESSOR HOFFMANN, of Dorpat, had to deal with

THE VARIOUS FORMS OF DIABETES.

Although he did not deny the possibility of the existence of "Lancereaux's

DIABETES PANCREATICUS,"

he had not been able to satisfy himself by experiment or clinical observation that this form exists independent of morbid changes other than those in the pancreas. He recognized two forms of the disease, the first of which was

ACCIDENTAL DIABETES.

This was generally of cerebral or neurotic origin, after traumatic, toxic, or psychical influences, for instance. The course of this form is light and rapid, and in a number of cases the pancreas is often affected. It may get well or terminate fatally in the course of two or three years.

CONSTITUTIONAL DIABETES.

This is the second form, and its prototype is the diabetes occurring in fat, and sometimes gouty, people somewhat advanced in years. Here we have furunculosis, carbuncles, cataracts, comatose symptoms, and renal complications in the course of the disease. The disease runs a decidedly chronic course, and recoveries are rare.

While there may be grave and light forms in accidental diabetes, he had found the constitutional diabetic disorder almost always grave. This is important as to the prognosis of a given case.

In the

TREATMENT OF DIABETES

we must always remember that all the diabetic symptoms are caused by glycosuria, and that our main object must be to cure the former by removing the latter.

The author does not consider an absolute nitrogenous diet essential, nor even compatible with the welfare of the patient. The alkaline remedies, the opiates, active muscular exercise, or muscular massage where the patient is not able to take active exercise, and the observance of a good hygienic régime in general, are the means he relies upon in treating his diabetic patients. Salicylic acid he finds useful in recent and comparatively light cases; in the severe and chronic cases its use is fraught with danger on account of its depressing effect upon the cardiac organs.

PROFESSOR VON MEHRING, of Strassburg, who had worked in the laboratory on the subject of glycosuria and

THE GLYCOGENIC FUNCTION OF THE LIVER

for a number of years, has of late succeeded in producing glycosuria in dogs by injecting phloridzin into a vein. Phloridzin, a glucoside known for about twenty years, is obtained from the bark of the roots of pear and apple trees. He used one gramme to every thousand grammes of the weight of the animal. Glycosuria is at once produced, no matter what kind of food is given to the animal. The same experiments made upon dogs that had been fasting for two weeks and more had the same results; also upon dogs previously poisoned by phosphorus, and after extirpating the pancreas. He removed the liver from geese (dogs do not survive this atrocious procedure), introduced phloridzin, and produced diabetes. These experiments would go to prove that the process of sugar-production may go on in the system independent of the formation of glycogen in the liver; further, that in the severer forms of diabetes the albuminates are transformed into carbo-hydrates and sugar. He found, again, that in such cases the

SECRETION OF UREA IS NOT INCREASED,

as it has thus far been supposed, until symptoms of acetonuria have developed.

Diabetes has a more or less prolonged period of latency in the blood before sugar appears in the urine. Von Mehring agreed with Hoffmann that an absolute diet is unnecessary in the treatment of diabetes, and has invariably noticed considerable decrease, and even disappearance, of sugar from the urine after prolonged active and passive muscular exercise.

PROFESSOR FINKLER had made similar experiments, and has the records of thirteen cases of diabetes, in which he succeeded in reducing the sugar in the urine from four hundred grains to one hundred and fifty grains and less per day by

ACTIVE AND PASSIVE MUSCULAR EXERCISE,

allowing the patients to take small quantities of the hydrocarbons with their food. In some cases the sugar disappeared entirely. Massage properly applied for some time makes the patients perspire freely.

BINZ, of Bonn, believed that butyric acid is the product which is the main cause of diabetic coma.

NAUNYN, of Königsberg, placed himself on the side of Cantani, Bouchardat, and Stokvis as to the propriety of restricting the patient to an absolute diet, and had had the most satisfactory results with it.

FRIDAY, APRIL 16TH—THIRD DAY.

The subject for discussion at this session was the

THERAPEUTICS OF SYPHILIS.

PROFESSOR KAPOSI, of Vienna, said that his large experience had led him to look upon syphilis, in opposition to Bärensprung and other writers, as one of the most easily manageable and often curable of the infectious diseases. The better results obtained to-day are due to our improved methods of rational, energetic, and protracted treatment of syphilis by inunction with the officinal *ung. hydrarg.*, or by hypodermatic injections of the various preparations of hydrarg. He himself had a preference for the inunction method according to Sigmund's plan, and began treatment with that in almost all cases.

The speaker first considered the question of

THE LOCAL TREATMENT OF SYPHILIS.

"Have we," he said, "as yet found any method of promise in the local treatment of the initial lesion of syphilis in a prophylactic way? Can we prevent the infection of the system by excision or caustic destruction of the sacral morbi?"

For a number of years he had tried excision of chancres, destroyed them with caustics, had used hypodermatic injections of iodine and mercury into and around the infiltrated inguinal glands, but the results had been almost always negative with regard to the prevention of syphilis.

Belonging to the class of unicists who, by the way, are quite in the minority in Germany at the present day, he experienced no surprise at his disappointment in his attempts to abort syphilis.

The second point was that of the

GENERAL PREVENTIVE TREATMENT.

Kaposi looked upon general treatment, commenced as soon as induration of the chancre (scleroma) had developed, as impracticable. The outbreak of syphilis will be protracted and irregular, and the course of the disease rendered less favorable as a consequence of such attempts. Early tertiary symptoms have often developed when such treatment was followed. It is, therefore, both futile and injurious.

The various remedies used in treating syphilis we must consider as to their power to remove the specific lesions, and again to prevent their return. To arrive at a correct estimate we must have

STATISTICS;

but hospital statistics are of no value in this instance, the patients generally disappearing from under observa-

tion when the lesions have been removed; private statistics are not now attainable, and it would be greatly desirable that physicians should do some collective work in gathering the results of treatment of syphilis in private practice over a certain period of years. The relapse again into secondary or tertiary symptoms is important in judging the efficacy of remedies.

THE INUNCTION METHOD

with *ung. hydrarg.* the writer considered to be the most efficacious and reliable means of treating early syphilis, and he preferred the plain ointment to all other preparations, including Liebreich's lanolin ointment, of which he had not seen as good and ready absorption as of the old salve, even with the addition of olive-oil to the lanolin. Local lesions, such as obstinate ulcers, infiltrated glands, superficial gummata, require local treatment also, and he recommended a well-adherent mercurial plaster for such purposes.

MERCURIAL BATHS

containing corrosive sublimate he used a great deal in the late forms of syphilis, such as rupia, etc., and with excellent results.

As to hypodermic injections, he believed with Bockhardt that those mercurial preparations are best which remain longest in the circulation. Emulsions of calomel may be used, as well as various sublimate solutions, with good results; but aside from the pain and frequent local disturbance which they often cause, he was satisfied that their efficacy in preventing syphilitic relapses is no better than that of inunctions—indeed, not as good.

The internal administration of calomel, sublimate, or protiodide of mercury he did not practise, but believed it to be efficacious.

Of all methods, the speaker found the inunction cure the best for the early forms of syphilis. In the later lesions iodide of potassium should be our main reliance. Even long-continued inunction with mercury produces no bad effects upon the system, but we must take care that the patient be properly fed, clothed, gets his warm baths, pays strict attention to his mouth and digestive organs, etc. Salivation must never be permitted. When this treatment is used assiduously, and with circumspection, hydrargyrosis and mercurial coloration of skin and mucous membrane will not take place. The mercury is constantly being eliminated, both with the fæces and the urine, and this elimination goes on for several weeks after treatment has ceased.

The iodide of potassium or of sodium was his remedy for the

TERTIARY LESIONS;

he began with 7½ grains, four times a day, gradually increasing the dose up to 30 grains, rarely more.

He did not favor heroic doses of these drugs.

In speaking of compound remedies, he said he had had much experience with

LITTMANN'S DECOCTION OF HERBS,

and praised it highly in the late forms of syphilis, particularly in obstinate ulcerations of the integuments. He often combined the inunction even with moderate doses of Littmann's compound morning and evening.

As to the so-called after-cures in the treatment of syphilis, he had not noticed any curative effects by the use of sea-baths, sulphur-baths, strict hydropathic treatment, etc.

The length of time required for the treatment of the early lesions varies according to their multiplicity and severity and the individuality of the patient. Kaposi advised long and careful treatment for from three to six months, and to repeat the cure only when relapses occur, not in order to prevent such, though he did not condemn the occasional repetition of a light course of treatment for safety's sake.

PROFESSOR NEISSER, of Breslau, hoped to see some good collective work done soon in order to establish the facillary character as important for diagnostic and prophylactic purposes of syphilis. Lustgarten's bacillus demonstration was probably correct, and was certainly very important. Being a dualist in his views as to syphilitic infection, he was in favor of destroying the initial lesion by excision, the active or galvanic cautery, or caustic chemical. Of the latter he preferred concentrated carbolic acid, as its application is safe, and not followed by inflammatory induration which might lead to diagnostic errors. His and others' results thus far in preventing syphilis by destroying chancres had certainly been encouraging, and he hoped that this procedure would be more generally practised.

WHEN SHOULD TREATMENT BE BEGUN?

None of us, he said, can tell in a given case whether it will run a mild or severe course, whether tertiary symptoms will come soon or late, or at all, no matter what treatment is instituted. We are agreed that the poison enters, generally incubates, and then spreads from the point of entrance and the neighboring vessels and glands. Why, then, wait with general treatment? Rather use every hour, every opportunity, for the prevention of the outbreak of syphilis and the destruction of its virus by local and general treatment, and begin with them at once. He agreed with Fournier that as mercurial treatment is curative it may also be preventive, and he began with it as soon as he had satisfied himself of the fact of the presence of an infecting sore. He further believed in treatment being continued for from two to three and four years, with suitable intermissions, and without regard to the presence or absence of characteristic specific lesions after the first period of latency. A chronic disease requires chronic treatment. Continuous treatment with small doses and proper intermissions was also, he said, practised abroad, particularly in America, if his information was correct, and has been found practical and salutary. As to the action of mercury, he would like to say, also, that it is proportional to the length of time it requires to be eliminated. He agreed with Kaposi as to the necessity of topical treatment of secondary lesions.

Among the materials in use for hypodermic injections he had found emulsions of calomel to be convenient and efficacious, although they caused some pain.

As to the dose of iodide of potassium, he gave as much as five drachms *per die* when there are urgent indications. He ordered the iodide in aqueous solution, or in milk, and found the latter vehicle quite convenient. When iodine, given by the mouth, did not agree with the patient, he injected hypodermically the tincture of iodine, or iodine in ether.

DR. LEONARD WEBER, of New York, was called upon by the Chair to open the discussion. He said that he appreciated the compliment paid to America in the invitation extended to him, and he thanked the gentlemen present in the name of his American brethren for the courtesy extended to him. He thought it might be of interest to his hearers to learn what are the main principles of treatment in use in the United States. The Americans recognized the great necessity of a rational, energetic, and long-continued treatment of constitutional syphilis; they treated the early forms with bichloride or the protiodide of mercury by the mouth, or by inunction with the gray ointment, and the late forms of the disease with iodide of potassium or of soda. The majority did not wait for the full development of constitutional syphilis before instituting general treatment, but began with it as soon as the diagnosis appeared to be secured upon the basis of induration of the sore and infiltration of the neighboring glands.

The mercurial preparation which the speaker used more than any other was probably the protiodide of mercury. The method of giving it in small doses for one, two, or more years, with suitable intermissions, has been introduced and urged by Keyes more than anybody

else in America. Many American physicians prefer the corrosive sublimate given by the mouth for the above purpose. The iodide of potassium or of soda is being given in the early forms also of syphilis, in the periods of intermission in the course of treatment with *hydrarg.*, and with advantage. In the management of relapses it is quite in vogue to order the patient to take a combination of mercury and iodide of potassium in solution. Experience has shown that in a series of cases of recurrent syphilis, with obstinate cutaneous and mucous lesions, better and quicker results are obtained by the so-called

MIXED TREATMENT

than by giving either of the two remedies alone. A minority of physicians—among whom was the speaker—prefer to begin general treatment with the inunction cure, carried out according to Sigmund's method. In a paper on "Locomotor Ataxia and Syphilis," read before the New York Academy of Medicine in 1884, and published in its "Transactions," and also in the New York MEDICAL RECORD in December, 1884, he said that his results with the inunction cure in the treatment of early constitutional syphilis during the last ten years of his practice had been better and more lasting than those which he had had during the previous ten years with mercurial preparations given by the mouth.

Hypodermic injections of mercury were not popular in America, and were not as yet systematically used by many physicians.

The favorable influence of Littmann's decoction of herbs upon some of the ulcerous forms of syphilis is not unknown in America; but the compound was not used as much now as in former years, when it was introduced to American physicians by Drs. Gescheidt and Detmold.

In serious and alarming cases of the later forms of syphilis, the iodide of potassium was generally given in rapidly increasing doses, and by some as much as five drachms and more *per die*. Van Buren, he believed, has introduced this method of giving large doses of the iodide. Seguin had of late emphasized it, and advised still larger doses, recommending, at the same time, that they be given dissolved in alkaline mineral waters immediately before meals. They are borne better by the stomach, he says, in this way, and he denies bad constitutional effects of such doses. The speaker did not think that a very large number of American medical men were convinced as much as Seguin of the necessity or advisability of these heroic doses.

In conclusion, Dr. Weber wished to say a few words with regard to fluid. calx. stilling. and other vegetable compounds which are recommended on and off by enterprising manufacturers in America as curatives to take the place of mercury or potass. iodide. Whenever such compounds have showed themselves as efficacious in the treatment of syphilis, such efficacy has depended, in his opinion, upon their purgative powers, and not on any inherent specific properties. With this remark he did not wish to hurt the great reputation which good fluid extracts of well-known drugs had made for themselves these many years. As Professor Leyden informed him some time ago, these American fluid extracts are beginning to find favor in Europe, and they well deserved it.

PROFESSOR VON ZIEMSSEN, of Munich, believed in early and long-continued treatment; he was not in the habit of giving heroic doses of iodide of potassium, and did not quite agree with the first speaker as to comparative benignity and sometimes ready curability of syphilis.

DR. SCHUSTER, of Aachen, spoke of the importance of controlling the continued elimination of hydrarg. by examination of fæces and urine for the presence of hydrarg. His remarks had been published in medical journals before, and he showed specimens of mercury obtained from fæces of mercurialized patients.

PROFESSOR LEUBE, of Würzburg, also favored the early and persistent treatment of syphilis.

PROFESSOR EDLEFSEN, of Kiel, also began treatment without delay, preferring the inunction cure. He was greatly in favor of the mixed treatment in suitable cases, whenever the therapeutic results do not come promptly in following out the inunction method. He was satisfied that considerable harm could be done by giving very large doses of iodide of potassium indiscriminately.

PROFESSOR BÄUMLER, of Freiburg, believed firmly in general preventive treatment, to be instituted with mercury as soon as the diagnosis is established. Believing in the bacillary theory of syphilis, he said the sooner we begin with destroying as many of the bacilli as we can by topical and general treatment the better it will be for the patient's future welfare. He advised iodide of potassium up to two and a half drachms *per die* in urgent cases only. Attention to the proper nutrition of the patient is of great importance in a disease which is capable of producing so profound a bacteria as syphilis.

DR. SCHUMACHER, of Aachen, recommended that every patient that had syphilis should be put through a course of specific treatment again before contracting marriage, though he might apparently be free from all symptoms.

SATURDAY, APRIL 17TH—FOURTH DAY.

The afternoon session of April 16th, and the last session on the morning of April 17th were devoted to the reading of short communications, presentation of specimens, patients, and new instruments and apparatus, and to executive business. The arrangements for social intercourse, dinners, etc., were excellent, the scientific meetings were all well attended, the discussions animated but courteous, and never personally aggressive; the speakers were generally to the point and spoke fluently, even eloquently, and Professor Leyden discharged the office of the President in an admirable manner. The Executive Committee also—consisting of Professors Leube, Jürgensen, and Dr. Pfeiffer—deserve praise for the very satisfactory way in which they had made all arrangements. On April 17th, at noon, the Congress adjourned.

THE FIFTEENTH CONGRESS OF THE GERMAN SURGICAL SOCIETY.

Held in Berlin, April 7, 8, and 9, 1886.

PROFESSOR v. VOLKMANN, PRESIDENT, IN THE CHAIR.

(Special Report for THE MEDICAL RECORD.)

THERE was a large attendance at the meetings of this Congress of Germany's best surgeons, and the profession at large was also well represented. The morning sessions were devoted to the presentation of cases, specimens, etc., and to the reading of short clinical communications, the regular papers, of which there were thirteen, being read in the afternoons. The latter did not contain any very startling discoveries, but were, nevertheless, full of interest and of considerable practical value.

DR. KRASKE, of Freiburg, read the first paper, on the

ETIOLOGY AND PATHOGENESIS OF ACUTE OSTEO-MYELITIS.

Rosenbach's microbe, "staphylococcus pyogenus aureus," held to be the specific cause of osteo-myelitis by some observers, can by itself and alone produce the disease in man. But other microbes, such as staphylococcus pyogenus albus, streptococcus, etc., may be of influence besides the "aureus." Such cases of mixed infection are particularly serious, and the demonstration of the various forms of micro-organisms is important as regards the prognosis of the disease. Finally, it is probable that every pyogenic microbe can occasionally excite acute osteo-myelitis. The specific microbe can enter through the skin, when inflammatory products are present in the integuments containing pyogenic staphylococci, through the lungs, and probably also through the alimentary canal.

But with the demonstration of the organized poison we have not yet arrived at an understanding of the real nature of the disease. As to the predisposing causes, it appears that an individual having had the disease once is more liable to be attacked again.

Professor Rosenbach, of Gottingen, then presented a communication on the

ETIOLOGY OF TRAUMATIC TETANUS IN MAN.

We have not yet, the author said, arrived at a satisfactory explanation of tetanus. There is no direct relationship between a wound and tetanus, although wounds containing foreign bodies, gangrenous wounds, and gunshot wounds of the thigh and leg, are liable to be followed by this accident. Dogs are refractory to inoculations with blood or pus taken from tetanic patients, but the same procedures yield positive results in rabbits, guineapigs, and mice, and the author found the specific microbe to have the bacillus form, and thought that it causes tetanus by the secretion of a strychnia and like poison.

Dr. Landerer, of Leipzig, followed with a paper on

TRANSFUSION AND INFUSION.

Direct transfusion of defibrinated blood, he said, has not yielded good results; somewhat better had been the success with the alkaline solutions of chloride of sodium recommended by Kronecker and Sander. But even this method was unsatisfactory, as the fluid introduced contained almost no nourishing material, and patients having lost about two-thirds of their blood (four and one-half per cent. of the weight of the body) generally died in spite of the infusion of the alkaline liquid.

The speaker took up transfusion of blood again, using defibrinated blood with four parts of an alkaline solution of chloride of sodium. With this solution he experimented successfully on animals first, and saved the life of one patient also. As much as 1,000 to 1,200 c.c. can be slowly introduced at one sitting without danger. Still better results are obtained by adding three per cent. of cane-sugar to the alkaline solution, which he did upon the suggestion of Professor Ludwig in Leipzig.

Professor Kocher, of Berne, read a paper on

EXTIRPATION OF THE THYROID GLAND,

in which he again drew attention to the fact, first brought forward by him three years ago, that extirpation of the entire thyroid gland in the adolescent will be followed by cachexia leading to idiocy, and he maintained that the operation should never be performed upon children and young persons.

Dr. König, of Hanover, presented a communication on

OPERATIONS FOR STONE IN THE BLADDER.

He advised the median perineal operation for small stones and small movable foreign bodies; sectio alba for large hard stones, encysted stones, large foreign bodies, and in cases in which a great number of stones are present. His success with "sectio alba" was anything but satisfactory, having lost four out of five cases. One of the fatal cases was that of a man seventy-five years old, from whose bladder were removed seventy stones, and thirty more were found post-mortem.

In the ensuing discussion, Bergmann, of Berlin, Roser, of Marburg, and Trendelenberg, of Bonn, were in favor of the high operation; Volkmann, König, and Schede of perineal section; and Ebermann, Schönborn, and Fürstenheim, of litholapaxy whenever practicable. Volkmann in particular recommended the "boutonnière," with which he had had most satisfactory results for many years.

It was the method practised by the empirics of former time, who relieved many sufferers, until the operation got into the hands of the scientific surgeons, who used the knife too freely and frequently lost their patients.

Bigelow's operation was highly spoken of, but it is not as frequently practised in Germany as it might be. The German surgeons are familiar with the splendid results obtained with Bigelow's method by Sir H. Thompson, but it appears the technique of that operation is found too difficult by the general surgeon here.

The last important paper was on the

TREATMENT OF LATERAL CURVATURE,

by Professor Landerer, of Leipzig. Lateral curvature, he said, is mainly produced by anomalous conditions of certain muscles of the spine. For the purpose of restoring those muscles to normal action, he has found massage more useful than gymnastics. The corset he has discarded altogether.

Dr. Volkmann agreed with the author of the paper as to the good influence of massage, but also employed the hot and cold douche applied to the back, and found the corset to be necessary for part of the day at least. Disturbed muscular action he thought was not the only cause of lateral curvature.

AMERICAN SURGICAL ASSOCIATION.

Seventh Annual Session, held at Washington, D. C., Apr. 28, 29, 30, and May 1, 1886.

[Continued from page 574.]

FRIDAY, APRIL 30TH—THIRD DAY—AFTERNOON SESSION.

The discussion of Dr. Keen's paper was taken up.

Dr. B. A. Watson said that this is a comparatively recent operation, and one with which we are not as yet perfectly familiar. We know very little as to the changes to which the cure is to be attributed. That nerve-stretching is advantageous in neuralgia and in certain cases of epilepsy and certain spasmodic convulsions had been demonstrated. Whether the relief is due to the gross changes in the nerve, to molecular changes, or to both, has not been thoroughly determined. In this particular case it would seem that elongation of the nerve possessed advantages over neurectomy. Neurotomy, even in the successful cases, gives but temporary relief. He could only commend the paper and the operation, and particularly the use of electricity for finding the nerve.

Dr. W. W. Keen thought that a large part of the effect of stretching is due to the gross mechanical disturbance of the nerve-trunk, interfering with nerve conduction, and a large element he thought was the physiological rest which is secured to the muscle. This at the same time aids in breaking up the vicious habit. The nutrition of the nerve is probably also affected.

Dr. C. H. Mastin, of Mobile, read a paper entitled

SUBCUTANEOUS DIVISION OF URETHRAL STRICTURE.

The history of the operation for external urethrotomy was first considered, and next was described the various methods which have been proposed for its performance. The objections to these were then gone into at length; the main objection to most of them is that they leave an open wound in the perineum to heal by granulation.

External urethrotomy is called for only under special circumstances. It has been laid down as a rule that where water can escape through a stricture the surgeon should always by patience be able to get an instrument through the stricture. The speaker thought there were exceptions to this rule.

The indications which render the operation necessary are:

1. The impossibility of passing a sound into the bladder through the urethral canal, where a firm organic structure blocks up the urethra, and dilatation or internal urethrotomy are not available.

2. In cases where a tight stricture has ruptured and an abscess has formed. Under such circumstances it is necessary to open the abscess, and it may be well to carry the incision farther and lay the stricture open.

3. Certain cases of old tight stricture complicated with urethral fistulæ through which the urine is passed in the act of urination. In almost all these cases, however, as soon as the lumen of the tube is restored, the fistulæ heal. The writer prefers internal urethrotomy in such cases.

4. A most important indication which may arise is rupture of the urethra by a blow, the effects of which are violent and severe.

5. Traumatic stricture, that is, where the stricture is the result of direct injury to the urethra. In these cases ordinary dilatation is inefficient and internal urethrotomy is often of little or no benefit.

6. A calculus impacted behind a stricture may be an indication for external section.

7. When extravasation of urine has occurred from sudden rupture of the urethra, and which is followed in a short time by extensive sloughing of the penis, scrotum, and groin.

8. The last indication is one in which Mr. Reginald Harrison recommends combined external and internal urethrotomy with the introduction of a large tube.

Having decided that external section is required, the question is which operation gives the best prospects of success and is most readily performed. The claims of the various operations proposed were then considered.

The author next described the operation which he had employed with entire satisfaction since 1868. The patient, being properly prepared, is put in the ordinary position for cystotomy. An anæsthetic is administered. A tube, open at both ends, is then passed down to the stricture. This protects the walls of the urethra, and puts on the stretch the face of the stricture. The tube is then filled with small whalebone probes, and one after another is tried with the hope that one will enter the stricture. This being accomplished the tube and probes are removed. The probe engaged in the stricture is then pushed forward and a Wheelhaus sound carried down to the stricture. An incision half an inch in length is then made in the anterior wall of the urethra, on the groove of the sound. The sound is withdrawn a short distance and the whalebone bougie sought for as it passes through the stricture and drawn out of the original wound. Over the probe a gorget is passed, having its blade upward. This is passed downward, cutting the stricture on its superior face. A catheter is then passed along the entire urethra into the bladder, and the urine evacuated. The stricture is then examined to determine whether or not any points of narrowing still remain. If there are, they are divided.

If, in the first instance, it is found impossible to pass the whalebone bougie, a staff with a deep groove is passed through the stricture and a small opening made. A whalebone bougie is then passed through the stricture and the operation is completed, as in the previous case. After operation a full-sized ordinary soft catheter is introduced to the prostatic portion of the urethra, but not into the bladder. The patient is put to bed on the left side, and directed to push the catheter into the bladder when the desire to urinate is felt, and to withdraw it beyond the neck of the bladder, but not through the stricture, after the urine has been passed. This is used only for the first twenty-four or thirty-six hours, to protect the wound from the contact of the urine. The speaker was opposed, on general principles, to allowing a catheter to remain in the bladder. At the end of the time mentioned the catheter is dispensed with. Immediately after the stricture has been incised and the calibre of the urethra restored, the external wound is closed with three fine pins, passing sufficiently deep to grasp the walls of the urethra. These are removed in from four to six days. In the course of eight or ten days the patient is able to return to his work. The maximum calibre of the urethra is restored by the use of graduated sounds.

The advantages of this operation are, the short time of confinement for the patient, the freedom from hemorrhage, the quick union by primary adhesion, and the small amount of cicatricial tissue left.

Dr. David Prince, of Jacksonville, Ill., said that he had seen enough cases to give him confidence in a particular method of treatment. About twelve years ago he became aware of the power of the negative pole of a battery to resolve neoplasms, and he had applied this principle with success to the treatment of stricture of the urethra. A catheter, connected with the negative pole of the battery, is passed down to the stricture, and the circuit completed by placing a sponge electrode, connected with the positive pole, over the sacrum, so that the distance between the two poles will be as short as possible. This treatment is frequently repeated, and in a number of cases he had found the result entirely satisfactory.

Dr. Dunott remarked that his experience in dealing with so-called impermeable or impassable stricture had not been small. He had been able to deal with them, even when there was great induration, almost without exception, by the ordinary internal urethrotomy operation. In fifty or sixty cases seen within the last twelve years he had been compelled in but one or two instances to perform external section. He thought the main reason that external urethrotomy is so frequently necessary is want of patience on the part of the surgeon. Almost without exception, where one drop of urine will pass through the urethra, he believed a guide could be gotten in, provided the surgeon had the patience to wait for it.

Dr. J. Ewing Mears offered an amendment to the by-laws, providing for the appointment of a committee of five, of which the President shall be chairman, to have charge of the preparation of the scientific work of each session. Laid over until the next meeting.

The President announced the following committee on the proposition looking to the formation of a Congress of American Physicians and Surgeons: Drs. C. H. Mastin, Charles T. Parkes, J. Ford Thompson, J. Ewing Mears, and N. Senn.

The officers elected were as follows:

President—Hunter McGuire, M.D., Richmond, Va.

Vice-Presidents—T. F. Prewitt, M.D., St. Louis, and J. W. Gouley, M.D., New York.

Secretary—J. R. Weist, M.D., Richmond, Ind.

Recorder—J. Ewing Mears, M.D., Philadelphia, Pa.

Treasurer—P. S. Conner, M.D., Cincinnati.

Council—Drs. Hunter McGuire, John S. Billings, L. McLane Tiffany, R. A. Kinloch, and Moses Quinn.

Honorary Members—Foreign, Sir William MacCormac; *American*, Professor Henry J. Bigelow.

Active Members Elected—Drs. H. H. Mudd, St. Louis, and Joseph Ransohoff, Cincinnati.

Time and place of next meeting, the second Wednesday of May, 1887, at Washington.

Adjourned.

The Microbe of Dysentery.—Drs. Condorelli-Mangeri and Aradas made a special study of an epidemic of dysentery occurring at Catane, and believe that they have discovered the specific microbe of this disease (*Rivista Internazionale di Medicina e Chirurgia*). The microorganism is a bacillus, and is found usually in long chains. It was constantly found in the dysenteric stools, and also in the air of the hospital wards in which the patients were received. The same bacillus was also discovered in the water of two wells from which the inhabitants of the village had drawn their supply. Experiments on animals also tended to confirm the belief that this microbe was the cause, or accompaniment, of dysentery.

Vaccination for Whooping-cough.—Dr. Entriken has vaccinated numbers of children suffering from pertussis, and claims by this means to have arrested the disease in almost every instance.—*Cincinnati Lancet and Clinic.*

MEDICAL AND CHIRURGICAL FACULTY OF THE STATE OF MARYLAND.

Eighty-eighth Annual Convention, held at Baltimore, Md., April 27, 28, 29, and 30, and May 1, 1886.

(Special to THE MEDICAL RECORD.)

(Concluded from p. 507.)

THURSDAY, APRIL 29TH—THIRD DAY.

THE Session was opened by the reading and adoption of the minutes of the previous day, after which the

REPORT OF THE SECTION ON OBSTETRICS AND GYNECOLOGY

was presented, the first paper being one from the Chairman of the Section, DR. B. BERNARD BROWNE, entitled

THE CURETTE, OR THE FINGER USED AS A CURETTE, AS A DIAGNOSTIC AND THERAPEUTIC AGENT IN GYNECOLOGY AND OBSTETRICS.

The following were the writer's conclusions: 1, The curette is an important diagnostic agent in all obscure affections of the uterus; 2, its use is less painful and less likely to set up cellulitis than the ordinary caustic and alterative applications; 3, it is more efficient than any other agent for the removal of intra-uterine growths; 4, after abortions its proper use will prevent hemorrhage and septicæmia; 5, after labor the antiseptic fingers or hand, used as a curette for the complete evacuation of the uterus, will lessen the dangers attending the puerperal woman, will prevent fetid lochial discharges, and hasten the period of involution.

DR. GEORGE M. MITTENBERGER then presented a communication on

PUERPERAL ECLAMPSIA.

He regarded this affection as not peculiar to the puerperal state, but as one occurring in other and widely separated conditions. Convulsions occur once in from three hundred and fifty to five hundred cases. The author did not believe that true eclampsia was always dependent upon renal affection, but held to the view of Seyfert, that albuminuria was in many cases the effect or the concomitant, and not the cause of the convulsions. In pregnancy, complicated with chronic Bright's disease, eclampsia was of rare occurrence. He believed that puerperal convulsions were due to changes in the medulla oblongata, the pathology of the disease consisting in increased or exaggerated excitability, irritability, or impressibility of this part, caused by continued and persistent irritation of the nerves of the genital apparatus. These are the peripheral causes; the central causes are intracranial congestion or anæmia, vitiated blood, and psychical influences, such as joy or grief. The cause being twofold, the treatment is the same. Of all sedatives to the nerve-centres, the writer regarded blood-letting as the most powerful and the most immediate in its effects. But it is, of course, only to be used in suitable cases. Veratrum, although inferior to blood-letting, acts in the same way as a vascular sedative. Chloroform is also of inestimable value, and is applicable to a greater range of cases. Chloral and morphine are also of great utility. The eccentric causes are also to be sought for and removed. Among prophylactic measures, chloral and the bromides, purgation when indicated, and absolute rest are recommended.

In the

DISCUSSION

which followed the reading of this paper, DR. P. C. WILLIAMS spoke strongly in favor of venesection, and he also advised the combination of jaborandi with the chloral.

DR. JOHN MORRIS also believed in the efficacy of blood-letting.

DR. LYNCH was a strong opponent of phlebotomy, and thought that veratrum viride would serve the same purpose.

DR. ARNOLD also opposed venesection, and thought potassium bromide was strongly indicated.

DR. ROBERT T. WILSON exhibited a

TEMPORARY CLAMP,

for use especially in ovariotomy, oöphorectomy, and Tait's operation.

DR. D. W. CATHELL reported a case of

LABOR COMPLICATED BY UTERINE FIBROIDS.

The Session was then adjourned.

FRIDAY, APRIL 30TH—FOURTH DAY.

The Session was opened by the reading, by the Chairman, DR. J. MORRIS, of the

REPORT OF THE COMMITTEE ON MEMOIRS.

Sketches were read of the lives of Drs. Richard McSherry, Edward De Loughery, Edward Schwartze, and Thomas Dougherty, members who had died during the year.

This was followed by the

REPORT OF THE SECTION ON MATERIA MEDICA AND THERAPEUTICS.

DR. RICHARD H. THOMAS, the Chairman, read a paper entitled

THE HOME TREATMENT OF ORDINARY PHTHISIS AS AFFECTED BY THE BACILLUS THEORY.

The author believed that isolation of phthisical patients was useless, for the infection is everywhere—in the dust of the street as well as in the patient's house. He thought the use of disinfectants about the sick-room was advisable, though great results could not be expected from this method. The endeavor to treat phthisis by specific antibacillary remedies, such as arsenic, had failed, but the plan of filling the room with antiseptic vapor, though somewhat difficult of execution in private practice, promised much better results. The hope of destroying the bacillus by this means, however, he regarded as vain. The speaker thought that phthisis was curable in certain cases, but no disease called for so much variety in treatment, and in none was routine, except that of fresh air, good food, and proper exercise, so out of place. As to the relation of the bacillus theory to the therapy of the disease, the author thought that the theory merely enforced what we knew before, and gave greater ground for hope in the ultimate success of our efforts. Its effect upon the profession had been to emphasize the necessity of prophylactic measures, of cleanliness, fresh air, and of hygienic treatment. The paper was discussed by Drs. Lynch, Grundy, and Morris. The next report was that of the

SECTION ON SANITARY SCIENCE.

The first paper, by DR. GEORGE H. ROHÉ, entitled

THE SANITARY RELATIONS OF FOOD,

was, in the absence of the author, read by title. DR. E. G. WATERS then read a paper on

SEWERAGE AND HOUSE DRAINAGE,

in which he drew a most alarming picture of the sanitary condition of Baltimore, with its subsoil saturated with leakage from the privy-vaults and cesspools, and compared the task of removing the filth and preventing its further accumulation to that of cleansing the Augean stables.

Adjourned.

SATURDAY, MAY 1ST—FIFTH DAY.

DR. O. J. COSKERY presented a communication entitled

THREE CASES OF [illegible],

which formed a part of the report of the Section of Surgery.

Dr. L. F. Morawetz then read a paper entitled

THE MIND IN STATU NASCENTE,

being the report of the Section on Psychology.

This was followed by a paper from the same Section, presented by Dr. John S. Conrad, and entitled

THE STUDY OF INSANITY.

The object of the communication was to show the necessity of including instruction on insanity and mental diseases in the curriculum of medical schools. The speaker said that the managers of public institutions in Maryland were obliged to import physicians from other States to treat the insane.

Dr. Whitfield Winsey read a paper on the

COMPARATIVE MORTALITY OF CONSUMPTION IN THE WHITE AND COLORED RACES,

in which he presented statistics showing the greater liability of the negro to suffer from pulmonary diseases, and urged that the members of this race be taught the necessity of attention to hygiene as a prophylactic measure.

The report of the committee upon the

SUPERVISION OF THE INTERESTS OF THE INSANE

in the State of Maryland was then presented by Dr. G. L. Taneyhill, secretary, in which it was stated that a bill had been drafted, which, after being revised by eminent legal authority, and adopted at a special meeting of the Faculty, had been passed by the Legislature. This bill, which is to go into effect on June 1st of the present year, provides for a

LUNACY COMMISSION

to have supervision over all institutions, public, corporate, and private, in which insane persons are detained. The board is to consist of the Attorney-General and four persons (two, at least, of whom must be physicians, and one of them experienced in the treatment of the insane) appointed by the Governor of the State. The commission is invested with all the functions and powers of law of coroners in the institutions under its control.

Dr. Philip C. Williams offered a series of resolutions complimenting the committee on its work, and thanking the able legal counsel for his valuable services, which had been rendered gratuitously.

Dr. Richard Gundry reported for the committee appointed to memorialize the Legislature on behalf of

A STATE INSTITUTION FOR THE EDUCATION OF IMBECILE AND FEEBLE-MINDED CHILDREN,

that a bill had been drafted, but had failed to pass the second branch of the Legislature. On motion the committee was continued, and Dr. S. J. Foot added to it.

The next report in order was that of the Section on Ophthalmology, Otology, and Laryngology, which was presented by Dr. John N. Mackenzie, the title of whose paper was

THE RELATION OF CERTAIN STATES OF THE ATMOSPHERE TO THE PREVALENCE OF CATARRHAL AFFECTIONS OF THE UPPER AIR-PASSAGES.

The atmospheric conditions were heat, cold, moisture, and air in motion. The author dwelt upon the influence of a changeable climate in the causation of nasal and laryngeal catarrh, and stated that there could be no doubt, in spite of some recently enunciated views to the contrary, that the prevalence of the latter depended in great measure upon the degree of the former. The effect of cold, he asserted, is frequently far from prejudicial, nasal inflammation often being mitigated or dispelled upon the appearance of frost. But excessive heat, on the other hand, may often usher in the catarrhal process, contrary to the popular impression. The association of moisture with heat or cold is especially productive of catarrhal affections of the nose and throat. The sudden passage from a cold or temperate condition to a hot and sultry state of the atmosphere is particularly irritating to the nasal mucous membrane. Under the head of "air of in motion" the author considered draughts, winds, and air-currents in general, as important agents in the determination of catarrhal affections, and concluded that in moist cold or moist warm air in motion are found the chief exciting causes combined. But it is not any one of these factors alone which is responsible for the prevalence of catarrhal affections so much as it is the change from one atmosphere to another.

Dr. Frank Donaldson, Jr., then presented a pneumatic cabinet, and made some remarks on

PNEUMATIC DIFFERENTIATION.

He said it was claimed for the apparatus that it improves nutrition and affects favorably the lesions in phthisical lungs. By it the patient secures the advantages of rarefied air on mountain-tops. He had not found that it tended to produce hemoptysis, but rather the reverse.

Dr. Claude Van Bibber presented a specimen of

MULTILOCULAR OVARIAN CYST.

After some miscellaneous business the

ELECTION OF OFFICERS

was held, with the following result:

President—Dr. G. W. Mittenberger.

Vice-Presidents—Drs. Thomas Opie and Richard Gundry.

Recording Secretary—Dr. G. Lane Taneyhill.

Assistant Secretary—Dr. Robert T. Wilson.

Corresponding Secretary—Dr. T. Barton Brune.

Reporting Secretary—Dr. Richard H. Thomas.

Treasurer—Dr. W. F. A. Kemp.

Executive Committee—Drs. P. C. Williams, John R. Quinan, H. P. C. Wilson, J. Edwin Michael, and James Carey Thomas.

In closing the Session, the President, Dr. Quinan, made some eloquent remarks. Referring to the subject of his annual address, he said the Faculty did not propose to throw any obtacles in the way of any persons or class of persons in the community, but only to resume the rights with which it had been invested by the Legislature in the control of medical practice in the State—for the good of both the profession and the public.

Adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 6, 1886.

Abraham Jacobi, M.D., President, in the Chair.

DERMATOLOGY DEMONSTRATED WITH THE STEREOPTICON.

The demonstration was made by Dr. H. G. Piffard, chiefly from photographs of living subjects suffering from various skin diseases. Dr. Piffard had made use of this form of demonstration at his lectures at the University Medical College, and had found it to possess advantages over the presentation of photographs for inspection by the students, and even over the exhibition of patients, whom only the students seated near the arena had an opportunity to closely inspect. The diseases illustrated were epithelioma, lupus, eczema, alopecia, favus, generalized melanosis, sarcoma, "barbers' itch," the eruptions of syphilis, of local poisoning, leprosy, elephantiasis, etc.; sections of the nails, of the skin in health and disease, were also exhibited. Some of the photographs were taken by the author of patients while in his office; others were by different artists, and some were presented to him by specialists in this and other cities.

The following proposed amendment to Article VIII., Section 1, of the constitution was read by The Secretary:

The Academy may suspend or expel a Fellow for violation of its regulations, or the commission of any act which unfavorably affects the character of the medical profession or the interests of the Academy.

Adjourned.

SECTION IN PRACTICE OF MEDICINE.

ALFRED L. LOOMIS, M.D., LL.D., CHAIRMAN.

DR. ROBERT J. DEVLIN read a paper (see p. 545) on

DIABETIC COMA.

DR. H. N. HEINEMAN opened the discussion by saying that he would present certain questions which, although they might not always represent the views which he entertained, might be worthy of consideration.

In the larger number of cases diabetics die from visceral complications, and in many of the recorded cases of death ascribed to diabetic coma the autopsies had revealed conditions which rendered the diagnosis very doubtful. When albumen was found in the urine, as well as sugar, the question arose whether or not the coma present, and in which the patient dies, should be called diabetic coma. Again, how much albumen should be allowed in the urine, and still the case be called diabetic coma, could not be determined, except by the examination of a large number of cases.

With regard to *acetone*, it might be present without immediate danger from diabetic coma; he had seen it in cases of pulmonary phthisis, without any evidence of sugar in the urine.

Again, might not the respiratory symptoms ascribed to diabetic coma in some cases be due to fat embolism of the pulmonary vessels?

Diabetes beginning after fifty years of age was very much more favorable than when it began between twenty and thirty, and the duration of the case was very much less than in either of the above classes when it began in children. Coma, therefore, would be most naturally found in young persons, because it occurred most frequently in the severe cases.

The response to the perichloride test was valuable in determining the liability to the occurrence of diabetic coma, but coma did not necessarily follow in cases in which the urine yielded this reaction.

In most cases of diabetic coma the sudden reduction in the quantity of sugar in the urine and the development of symptoms of coma were associated. At the same time, we were in the dark with regard to the exact nature of the mode of death in these cases, as we were with reference to the causation of diabetes, and were in a position very much like that we occupied concerning uræmia. He regarded Dr. Devlin's paper as the most complete article on this subject which had yet appeared.

He would ask Dr. Devlin if it had been determined that the administration of the carbolic group had any marked effect in reducing the quantity of sugar in the urine? and the importance of the question existed in the fact that these drugs produced, of themselves, symptoms analogous to those present in diabetic coma.

DR. DEVLIN said that he had not directed his attention to the last question suggested by Dr. Heineman. He regarded it as an easy thing to get deceived with reference to the frequency of diabetic coma, if reliance was placed upon statistics obtained from the profession at large. With regard to the existence of fat embolism in certain cases, he thought so little was known about this condition that a safe estimate could not be made concerning its influence. With regard to *acetone*, he was not at all certain that its presence had any special significance.

DR. KINNICUTT said that he believed with Dr. Devlin that it was very difficult to accurately determine the percentage of deaths from diabetic coma in diabetes. Many cases of diabetic coma were undoubtedly unrecognized—a striking instance of this kind had come under his notice. A lady, apparently in good health, suddenly developed great restlessness, rapidly followed by drowsiness and coma, death ensuing in twelve hours from the appearance of the first symptoms. Only by an examination of the urine withdrawn from the bladder after death, and the discovery in it of a large amount of sugar, was the probable nature of the attack recognized. The presence of a small amount of albumen in diabetic urine, in the absence of previous symptoms of renal affection, he should not regard as a sufficient basis for regarding the existence of coma of uræmic rather than of diabetic origin. Although the clinical picture of these varieties of coma was quite different, as a rule, nevertheless, there were cases which permitted of a doubtful interpretation. In such cases, the presence or absence of increased arterial tension might be of service in a differentiation. In the vast majority of instances, the former condition obtained in uræmic coma, the reverse in the coma of diabetes. Dr. Kinnicutt was inclined to believe that many factors, acting in varying combinations and degrees of intensity in different cases, were concerned in the production of both diabetic and uræmic coma.

DR. HEINEMAN said he used the term *acetone* as standing for a group of products found in the urine. He agreed with Dr. Kinnicutt that the simple presence of albumen in the urine should not throw the case out of the class of diabetic coma, as the presence of albumen and hyaline casts from time to time did not at all signify that the kidneys were involved.

THE CHAIRMAN said that during the last three years he had had one case each year of diabetic coma, occurring in the hottest weather in July. Whether the temperature had anything to do with the development of the fatal condition or not, he was unable to say. It was a coincidence, at least, which to him was interesting, especially as he had seen only five cases of diabetic coma, and these occurred during the hottest weather in the month of July.

DR. DEVLIN said that he could recall only one reported case which seemed to have any relation to hot weather.

The Section then adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 14, 1886.

JOHN C. PETERS, M.D., PRESIDENT, *pro tem.*

DR. G. C. FREEBORN presented, in behalf of a candidate, a specimen of *colloid carcinoma of the caput coli.*

DR. W. P. NORTHRUP presented, in behalf of a candidate, a specimen of *chronic localized endocarditis.*

DR. W. M. CARPENTER presented, in behalf of a candidate, a specimen of *renal calculus* weighing one hundred and forty grains.

REPORT OF THE COMMITTEE ON MICROSCOPY.

DR. G. C. FREEBORN, from the Committee on Microscopy, reported on the tumors removed from the abdominal wall by Dr. Sims, and presented at the stated meeting of the Society held March 10th. The growths had the gross appearance of little nodules of fat. On microscopical examination they were found to be surrounded by a fibrous capsule to about one-third of their extent. Two of them contained marked hemorrhage, and one contained quite a large mass of sarcomatous new-growth, and extending through the fatty portion were fibrous processes containing new vessels, and the whole was surrounded by sarcomatous tissue. Nerve-fibres were found in three of the nodules, and in one they were completely infiltrated with small round and spindle-shaped cells. The diagnosis was fibro-sarcoma, probably arising from the nerves.

Dr. H. Marion Sims presented a specimen which illustrated

A PECULIAR CONDITION FOUND AT AN OVARIOTOMY.

The woman was sixty-three years of age, who had enjoyed a fair degree of health until within the last five years, when she noticed an enlargement of the abdomen for which she consulted a surgeon, who tapped her and drew off quite a large quantity of fluid; she was also tapped twice afterward, and before Dr. Sims saw her. At the time when Dr. Sims first saw the patient she was anæmic and was losing flesh rapidly, and he decided to give her temporary relief by tapping the abdomen again and then endeavoring to improve her general condition. He drew off six quarts of a thick fluid, but she did not materially improve. The abdomen began to fill again, and he determined to operate at once, notwithstanding her enfeebled condition. As soon as he made the incision into the abdomen he reached what he took to be the sac of the tumor, and, finding it firmly adherent to the abdominal wall, he began to separate it. After separating it for about two inches he came to a sudden termination of this apparent wall of the sac, and, on closer inspection, he found that he had to deal with a broad band about four inches wide, which he continued to loosen from the abdominal wall, and finally pushed it up to one side, when he exposed the real sac. The tumor had very extensive adhesions, and was removed with a great deal of difficulty, also rather profuse hemorrhage, and was found to be a sloughing ovarian tumor.

The broad band was attached to the symphisis pubis and to the bladder, from which Dr. Sims dissected it. At its lower extremity it was quite thick, and as it extended upward it became thinner and thinner until it neared the umbilicus, where it was about as thin as ordinary blotting paper; throughout its whole extent it was not particularly vascular. He was unable to give an opinion concerning its exact nature, and at his request the specimen was referred to the Committee on Microscopy.

The Society then went into executive session.

Correspondence.

THE DRINKING-WATER OF NEW HAVEN, CONN.

To the Editor of The Medical Record.

Sir: In The Record of April 3d I notice an abstract of some criticisms on my investigations into the quality of the drinking-water of New Haven, Conn.

Your editorial affords the first information that Professor Smith, desirous of demonstrating his dexterity in the matter of water-analysis, is urging this superiority by an endeavor to impugn the accuracy of my figures; this aim has sadly marred and mystified his results.

Dr. Smith is, of course, fully aware of the vast difference between *grains per gallon* and *parts per million*; yet, that which is tabulated by me in *grains per gallon* I find placed side by side with his figures in *parts per million*, and *vice versa*; whether or no this change was necessary to produce the great discrepancy claimed by him is immaterial, but I do protest against such a twisting of figures.

Each one of the four analyses I made were carefully verified by a repetition of the work, and, apart from the slight difference which invariably occurs in such cases, the figures given in my report are sufficiently accurate for all practical purposes. I regret to be compelled to differ with Professor Smith, but it does seem to me that the results I arrived at from eight examinations should, to say the least, be as precise as those of the doctor, whose opinion seems to have been formed from a single analysis of the water.

It is an established fact that the quantitative relation between the total solids in the water in different portions of the same supply are subject to the greatest variation; this is also true of the other constituents, and is particularly so in such reservoirs as those from which New Haven obtains her water. Not only is this found in different portions of a pond from which the samples for analysis may be taken, but also in different depths. Dr. Cameron cites a case wherein the amount of solids at the surface were 29 grains to the gallon, and 47.4 grains at some depth; the quantity of chlorine in the first equalled 2.1 grains per gallon, and in the second water from the same source 1.7 grains per gallon. It does not follow, therefore, that because the water analyzed by Dr. Smith was obtained from the same reservoir, it must be of the identical quantitative composition (as far as solids and chlorine are concerned) as were the specimens sent to me.

I estimated the solids in each sample of water in a very careful manner; and when it is remembered that the weighing was done twice in each case, it will be easily seen that any inaccuracy which might have been committed in the first would certainly have been discovered at the second trial. I think, therefore, that the water analyzed by Professor Smith and that sent to me were not from identical localities, as he has claimed.

Less than a grain of chlorine to the gallon will not make itself apparent when we test the water qualitatively (this I always do before making any quantitative analysis). Now, the fact is, that each one of my samples became immediately turbid when the solution of argentic nitrate was added. This indicates an excess of chlorine, which the quantitative test demonstrated to amount to *seven grains to the gallon*. The rest of the examination shows this excess of very small moment, because the water contains no sewage contamination or animal excreta. Other and harmless sources of salt are certainly abundant in such close proximity to salt water as is the impounding reservoir from which New Haven is provided with water, yet Dr. Smith finds less chlorine here than can be found in any other place in Connecticut. This statement should be taken *cum grano salis*, and perhaps the addition of two or three grains would be nearer the mark.

I made the investigation with the object of determining whether or no the water in the reservoirs was at the time in proper sanitary condition. This being the main and all-important feature, it remains for us to see whether I reported correct results to Professor Lindsley. Dr. Smith does not mention this; he contents himself with his attempt to throw doubt upon the accuracy of my figures, knowing nothing of the specimens of water from which they were made, and calls the work of Professor Chittenden to his support, when, in fact, the latter gentleman personally informed me, in conversation a little while ago, that it had been several years since he had given any attention to the chemical condition of the New Haven water. What Professor Chittenden's analyses, made years ago, have to do with the sanitary condition of the water last summer, I do not clearly understand.

In short, this mathematical hair-splitting "has nothing to do with the case." I attached no importance whatever to the large excess of chlorine which I found. It did not arise from or accompany sewage or animal polluting substances of any kind, and, for all I *know* or *care*, may have been a normal constituent of the water, or may have had an entirely foreign origin (as imperfectly washed bottles in which the specimens were forwarded to me). I did not collect the water, nor was I furnished with any information as to how or by whom it was obtained. Of this I am certain, however—there were in each of the four samples *seven grains of chlorine to the gallon*.

I look upon the chemical examination of water for this purpose, unless accompanied with a thorough microscopical investigation, as of little importance. The determination of the solids is at best a "rough one, and

the solid matter does not exactly represent what was originally in solution," while there is a vast difference of opinion as to the proper temperature which should be employed in the operation; some chemists use as low a degree of heat as 140° C., while others are in the habit of heating to 180° C.; this, of course, would produce great diversity in the weight of the solids. There are many other factors which we might urge in explanation of the difference between the quantitative results of two observers, but I do not wish to consume valuable time.

The essential features of the investigation and the facts upon which I based my opinion of the water were: A small amount of *free ammonia* (less than that found by Professor Smith) and a considerable quantity of *albuminoid ammonia*. From a large experience with the sanitary analysis of water (extending over twelve years), I have found that this condition points to the *vegetable* nature of the organic impurities. In this case the microscope demonstrated that I was correct. This most important step in the analysis showed the particular vegetable matters with which the water was contaminated. I therefore stated, in my report to the secretary of the State Board of Health, that although it was a *usable* water, it was "by no means up to the local standard of purity," and might cause severe diarrhœa in summer; while, the connection between such water and malarial diseases being suspected, we could not sanction its employment without proper treatment.

Dr. Smith's analysis shows that the water which he examined was in exactly the same condition. It perhaps originally contained more organic matter than any of the samples sent to me; for if it was not examined in a fresh state, the confervoid growths, etc., which would form very rapidly in warm weather would feed upon the free ammonia, and thus diminish its quantity in a short time, besides other changes that may have taken place.

Professor Smith certainly does not wish to be understood as saying that water which contains *twice* the amount of *free ammonia*, *three times* the quantity of albuminoid ammonia that should be found in water of *ordinary* purity, besides overwhelming evidence afforded by the microscope of organic impurities, is a water which is beyond suspicion. Yours respectfully,

ARTHUR J. WOLFF, M.D.

HARTFORD, CONN., April 15, 1886.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE BARTLETT TRIAL—SCIENTISTS IN A CORNER—MISTAKES ABOUT CUCA—TEN THOUSAND PRESCRIPTIONS—HYDATID CYST OF RECTO-VESICAL POUCH—RHEUMATOID ARTHRITIS NOT A DISEASE—DEATH OF DR. EVORY KENNEDY.

LONDON, April 28, 1886.

MANY of the details of the "Bartlett" trial are probably already known to your readers through the reports which have doubtless appeared in the columns of the American newspapers, whose efficiency in reporting news is well known to me. It would therefore be telling a tale already told to rehearse the story of this famous trial. It has, however, some features of medical interest. One of these is, that it is the first case in which it has been suggested that a murder has been committed by the internal administration of liquid chloroform. In connection with this the old question has been raised of whether a sleeping person can be anæsthetized by the inhalation of chloroform vapor without awakening him. At one stage of the trial it was insinuated that the accused had done this to the prisoner, and then poured chloroform down his throat. An obvious difficulty in the way of the acceptance of this theory was that complete anæsthesia would annul reflex action and prevent deglutition. Every theory offered was, in fact, beset with difficulties, and the whole case so bristled with anomalous features that it is not much to be wondered at that the jury acquitted the widow.

A great deal was said, both in and out of court, about the extraordinary sexual, or rather non-sexual, relations of Mr. and Mrs. Bartlett. They had been married over ten years, but it was alleged that their union had been purely platonic, and that this arrangement had been made between them by the wish of Mr. Bartlett, who had imbibed peculiar notions not only on this, but on many other subjects. On one occasion, indeed, this arrangement had been departed from at the wish of Mrs. Bartlett, who was anxious to have a family, and a still born child was the result. This story excited much comment and was evidently disbelieved by the judge, who remarked on the finding of certain preventives in the pockets of the deceased. But probably many medical men could recall similar instances which have come under their observation. Dr. King Chambers records one in his work on "Indigestion," though the arrangement was not entered into *ab initio*.

Some of the scientific witnesses did not fare very well in court. The medical man who attended the deceased was very severely handled by the judge. A London physician, Dr. T. H. Green, who was called as a witness, had to confess that he was not aware that it had been believed that chloral hydrate could be converted into chloroform on being taken into the blood and meeting with the alkali of the latter fluid. As Liebreich's original theory has now been refuted by Hammersten, it would have been excusable to have said he did not believe in it, but a hospital physician of standing and a graduate of the much-vaunted London University should surely have known it, if only as a chemical question.

A dental surgeon who was examined was asked about cocaine, a drug which he had applied to the gums of the deceased. He acknowledged that he did not know whether cocaine was a vegetable or mineral drug, and on being asked by the judge whether it was not the active principle of the cocoa-nut, could give no answer. A dental surgeon may be excused from knowing all about cocaine, and a judge may be so still more; but what shall be said of a hospital surgeon who writes on the subject as an authority and simply "puts his foot in it." Such, at least, is the expression which should be justly applied to a writer who muddles up cocoa, the cocoa-nut, and coca, and appends to a description of cocoa the botanical characters of erythroxylon coca. Another writer abuses the *British Medical Journal* for adopting Sir Robert Christison's suggestion to term the plant cuca (instead of coca), and its active principle cucaine. Had the learned baronet's suggestion been generally adopted, I scarcely think the surgeon I am alluding to could have so deeply committed himself. He actually puts down theobromine as an active principle of the erythroxylon coca.

The *Chemist and Druggist* has been holding a symposium of prescriptions. With a view of ascertaining what drugs are prescribed most frequently, it has invited its readers to send prescriptions. Thirteen thousand prescriptions have been sent, and from these the editors have selected ten thousand and analyzed them. With a view of adding interest to the matter, they have offered a prize, for competition among their readers, for the one among them who shall guess most correctly the six drugs most frequently prescribed. The editorial analysis of the ten thousand prescriptions has revealed that the six medicines most frequently prescribed are: Sp. chloroformi, pot. bromid., vin. ipecac., sp. ammon. aromat., quininæ sulph., and sodæ bicarb. The order is that of frequency. The second six most frequently prescribed were found to be: Ammon. carb., liq. ammon. acet., glycerine, syr. aurantii, pot. bicarb., sp. æth. nit. Proprietary articles only amounted to a little over seven hundred out of ten thousand prescriptions. The six principally prescribed proprietary articles were found to be: Vaseline, chloro-

dyne, nepenthe, Fellows' syrup, Benger's liquor pepticus, liquor carbonis detergens. These collectively constituted nearly two-thirds of the proprietary articles dispensed.

At the last meeting of the Pathological Society, Mr. Hurry Fenwick showed a hydatid cyst of the recto-vesical pouch removed from the body of a man about fifty years of age. Only about fifty cases of hydatid tumor in this situation are on record. In this case a hydatid cyst was also found in the liver, and Mr. Fenwick said the most probable explanation of these cases was leakage from a hepatic cyst.

Mr. Arbuthnot Lane brought up again the subject of rheumatoid arthritis. After referring to a previous paper in which he had endeavored to show that Charcot's disease was modified rheumatoid arthritis, he now put forward the opinion that the latter affection is not a disease, but the result of traumatism. He had shown (in previous papers) that the transmission of pressure produced many important changes in the bones and joints. Rheumatoid arthritis was common in man, compared with the lower animals, because he often bore burdens whose weight was transmitted at great mechanical disadvantage, and his joints were more exposed to injury than in the lower animals. In animals which carried or dragged heavy burdens (*e.g.*, horses), pressure changes were often seen. This was less frequently the case with animals, portions of whose bodies are exposed to violent strain in pursuing their prey.

Evory Kennedy died last week in London. This once famous obstetrician retired from practice many years ago, and, living in a western suburb of London in comparative retirement, had almost lost touch with the present generation. To many London doctors, in fact, the announcement of his death will be the first intimation that he ever lived among them. Yet, perhaps no name was more familiar to the obstetricians of the last generation. Dr. Kennedy graduated at the University of Edinburgh as long ago as 1827, and was therefore an octogenarian at the time of his death. He was one of the early workers in the field of uterine auscultation, and discovered the funic, or, as he termed it, placental, souffle in 1830. In 1834 he published a treatise entitled "Obstetric Auscultation, or Means of Detecting Life or Death in the Fœtus before Birth." He also wrote on vesico-vaginal fistula fifty-three years ago, and on inflammatory affections of the uterus thirty-nine years ago. He was president of the King's and Queen's College of Physicians of Ireland in 1854–55. He had previously held the important post of master of the Rotunda Lying-in Hospital. In later years, when about to retire from practice in Dublin, he took a very active part in advocating some important alterations in the sanitary arrangements of the Rotunda.

THE LATE DR. AUSTIN FLINT.—At the meeting of the Medical Board of Charity Hospital, held May 1, 1886, the following preamble and resolutions were unanimously adopted, and it was voted that copies be sent to THE MEDICAL RECORD and *The New York Medical Journal* for publication :

Whereas, It has pleased God to remove from his field of labor our distinguished colleague, the late Professor Austin Flint, M.D., LL.D., whose lofty conception of the functions of a physician in his relation to his patients, and whose noble attributes as a man are enshrined in our memory ; and,

Whereas, His sudden death, when yet active and in the zenith of his fame as physician, teacher, and zealous worker in the field of scientific research, and who in death is remembered and ennobled by the record of his qualities and deeds as the acknowledged representative of all that is best in the study and practice of medical science and art ; therefore be it

Resolved, That the Board of Physicians and Surgeons of the New York Charity Hospital herewith express its deep sense of loss in common with the medical profession.

Resolved, That its members respectfully tender its sympathies to the family of the deceased.

Resolved, That these resolutions be entered upon the secretary's minutes, on a page designed for the purpose, and that a copy be sent to the family of the late Professor Flint, and to the Honorable Board of Commissioners of Public Charities and Correction.

THOMAS H. ALLEN,
CHARLES W. ALLEN, F. R. STURGIS,

ANTIPYRINE.

By J. H. FRANKENBERG, M.D.

LATE HOUSE PHYSICIAN TO LUTHERAN HOSPITAL, ASSISTANT TO PROF. [illegible] SURGICAL DISPENSARY, NEW YORK.

ONE of the most recent contributions to our materia medica by synthetic chemistry is a derivative of chinoline, and has been very appropriately denominated antipyrine. It was discovered by Knorr, of Erlangen, and physiologically experimented with by by Filehne, of Berlin.

The drug has had a very wide field of trial, not only in Germany, and all over the European continent, but also throughout this country. A very large number of reports of cases are on record. They are almost unanimous in their verdict. Antipyrine is an antifebrile remedy which will cope with, and in our judgment surpass, any other antipyretic means that we possess at the present day. It is a drug which answers nearly all the purposes and requirements that could be desired of an antipyretic.

It is applicable to almost all cases with febrile movement; it acts with safety and certainty; it is a most powerful agent in this respect, and its effects can be graduated approximately, and prognosticated according to the amount administered. The reduction of the temperature is lasting, and accompanied by few or really no objectionable features.

It first made its appearance in June, 1884. It is a white crystalline powder, of a slightly yellowish tinge, readily soluble in alcohol and water; two parts of antipyrine will dissolve in one part of hot water, and very little of the salt will be deposited on cooling. It is slightly bitter in taste, and can readily be taken in solution disguised by a drop of the oil of peppermint or other aromatic, or it may be taken in wafers.

On taking fifteen grains in health, there is no effect shown except that the temperature may be reduced 0.3 or 0.4 of a degree, and a feeling of bodily warmth experienced. If thirty grains are taken, the temperature is reduced about one-half degree; the pulse-rate is not altered, although its character is slightly changed; the arterial tension is elevated, and the pulse-beat becomes more abrupt and sharp. The body becomes bedewed with a light perspiration at the end of thirty to forty-five minutes, and is followed by a feeling of apathy and languidness.

On taking forty-five grains, the same symptoms persist to a slightly more exaggerated degree. The feeling of *ennui* becomes more marked, although drowsiness does not usually prevail. The respiration is not at all affected, and the temperature may sink from 0.6 to 0.8 of a degree.

In poisonous doses, given to animals, Demme, of Berne, found that it acts on the nervous system by selection, at first producing general tetanic spasms, and finally death by cardiac paralysis.

The drug is eliminated through the skin and urine chiefly. It makes its appearance in the urine very soon after administration, and reaches its maximum in the course of one or two hours, and gradually disappears after twelve hours, which seems to indicate, as it happens, the length of time during which it exerts its physiological effects. Its presence in the urine is recognized by the dark-red color produced by the addition of a solution of the chloride of iron. It may also be detected by adding nitric acid to the urine, which turns the solution to an emerald-green color.

Now, passing to its effects in disease, we find that if thirty grains be given to a patient with febrile movement, in about twenty minutes the skin becomes somewhat reddened and moist, the superficial veins present a congested appearance, and a profuse perspiration is set up. In one case that was weighed, the loss of bodily weight amounted to over one and a quarter pound in the course of two hours after the first administration of thirty grains. Accompanying this derivation of the blood from the interior to the circumference there is a corresponding reduction of the internal temperature. In several cases we recall a discrepancy of over 2° F. between the rectal and axillary temperature.

The rapidity of the pulse is diminished during the administration of antipyrine, but comparatively less than the temperature. The ratio existing between the temperature and pulse before and after the exhibition of the drug is not the same. It has a more decided effect on reducing the temperature than on the pulse. The pulse-beat is more tense and less compressible. If given to a patient with a dicrotic pulse, the dicrotism, that is, the secondary wave, disappears entirely, or nearly so. This we have verified with the sphygmograph in a number of cases of typhoid fever.

The return of the temperature, just as its disappearance, is slow and gradual in most cases, covering from three to six hours. This slow accession to temperature in most patients accounts for the absence of chills or chilly sensations, which take place regularly before the recurrence of temperature when kairin has been administered.

As for its objectionable traits, we find that particularly enfeebled women and children will at times complain of nausea, and even vomiting will ensue. Marked somnolency has occurred after using the drug in a few instances.

To avoid the possibility of upsetting the stomach we have tried, as others, the hypodermatic use of the remedy. As it is so readily soluble in hot water, a very concentrated solution can be made. We have found these advantages in using the drug hypodermatically: It requires only one-half to one-third the amount of antipyrine; it avoids all gastric disturbances, and acts more rapidly and more certainly. We have used it repeatedly, and have not observed an abscess or severe inflammation follow. It does not seem to be irritating, as the patients do not particularly complain when the drug is injected. This mode of administration is not to be enjoined in either very delicate children or very much debilitated persons, as the reduction of temperature may be too sudden and too great, and symptoms of collapse may possibly supervene.

Last winter we made a series of experiments on the urine of a patient taking antipyrine, and found that the amount of nitrogen, which is an exponent of the amount of urea, was considerably diminished. And contrasting our results with those of Sassetzky, who made similar experiments on the urine of patients taking quinine, salicylic acid, and cold baths, we concluded that the elimination of nitrogen through the urine was most reduced when antipyrine was exhibited. This proves *à priori* that antipyrine has a greater influence upon reducing the chemico-vital changes than either of the other antipyretic measures.

The experiment consisted of giving the patient, who was in the third week of typhoid fever, daily, the same amount of milk and beef-tea. The experiment lasted seven consecutive days. On the first day the patient received seventy-five grains of antipyrine, on the fourth day ninety grains, and on the fifth and sixth days seventy-five grains daily; on the other days no antipyretic measures were adopted.

AMOUNT OF NITROGEN ELIMINATED AFTER USE OF ANTIPYRINE.

Day of trial	1	2	3	4	5	6	7
Amount of antipyrine	75 grs.	none.	none.	90 grs.	75 grs.	75 grs.	none.
Average temperature	101	103	102.5	100	101.5	101	102.9
Cubic centimetres nitrogen eliminated.	17.51	22.81	20.23	12.02	10.82	10.45	23.49

As the table shows, during those days on which antipyrine was administered a much less amount of nitrogen was eliminated from the body, an average of 6½ c.c. of nitrogen, which denotes a saving of nine ounces of muscle. The amount of nitrogen was determined by the use of the hypochloride of soda. These experiments correspond with those made by Müller (*Centralblatt für klin. Med.*, 1884, p. 36).

The drug has been employed, either by ourselves or fellow-colleagues who have accurately reported their results, in about one hundred cases. It has been exhibited in cases of typhoid fever, in acute lobar and bronchopneumonia, scarlatina, peritonitis, meningitis, puerperal fever, acute articular rheumatism, erysipelas, intermittent fever, acute and chronic phthisis, and in cases of insolation.

Among these patients some had very high temperatures, as high as 108.6°, but the average ranged between 102° and 105°. In all these cases the temperature was safely reduced at least two degrees, and in some six to seven degrees, on the average from four to five degrees. In the first score of cases that the drug was used, we tried the tolerance of the patient by beginning with fifteen grains, which we still continue to do in weak individuals. If the remedy agrees with the patient, then thirty grains are administered, and continued until ninety to one hundred and twenty grains have been consumed in the course of the day, if the temperature calls for it.

We have found in this drug, employed in this manner, a sure and most powerful means of reducing temperature, and we have succeeded in the great majority of cases so doing either to the normal standard, or nearly so, when on those days during which no antifebrile measures had been adopted the temperature oscillated between 103° and 105°.

The effect of the antipyrine varies largely with the severity of the illness. If the disease be one of moderate intensity, the time elapsing between the minimum and the maximum temperatures, after its administration, varies from three to six hours. In severe cases, with obstinate temperatures, we have found only a short intermission, or only a remission in the temperature.

As recommended by Filehne, the remedy was given in thirty-grain doses, repeated every hour, until three or four such doses had been taken. This plan was followed in quite a number of cases, more especially in cases of typhoid fever and pneumonia with temperatures over 104°; a complete or almost complete subsidence of fever was observed for ten to fifteen hours in many cases, and in individual instances for a much longer period of time. The first impression would be that this mode of dispensing the drug was highly advantageous, still the end justifies the means. In one case the temperature sunk from 103.5° to 96°, in two other cases of typhoid from 104° to 95°, and in one case of pneumonia from 103.5° to 95.6°. Notwithstanding these marked depreciations in temperature in a comparatively short time, no symptoms of collapse were manifested. The pulse remained good and the mind clear, and no great discomfort was experienced. In but one case of advanced phthisis do we recall the occurrence of cyanosis while the temperature was subsiding, and even here it was but transient; no other alarming symptoms were evinced.

The method of administering the drug, just detailed, we have found too bold even in hospital practice, where the patient is constantly under the eye of the physician or trained nurse; hence much less can such dosage be advocated in private practice.

It has consequently been our custom to make each individual case a study, and apportion the drug accordingly. In cases of typhoid fever or acute lobar pneumonia occurring in young healthy subjects, thirty grains were given, and the effects carefully observed. If the temperature was coming down rapidly, the drug was either withheld or only fifteen grains were given at the end of an hour. If, however, only a slight impression was made on the temperature, then thirty grains were again given, and the observation continued. Sometimes one dose would suffice, at other times seventy-five grains would have to be given in the course of three or four hours. In still other cases the same amount would be distributed over five or six hours. Though we have observed that when the doses were given at too long intervals a complete apyrexia would not occur, still an adequate reduction would take place to render the patient more comfortable.

From experience we know that some patients bear temperature much better than others, irrespective of the general physical conditions. Some patients with a temperature of 104° will feel quite at ease, the mind will be clear, and the patient will complain of no subjective symptoms; whereas in others a temperature of 102° will render the patient very restless, hot, and even delirious. This we have found very difficult to account for, and can only ascribe it to individual idiosyncrasies.

Now, in the first class of cases a complete apyrexia is hardly necessary, while in the second it is exceedingly desirable. Hence the administration of the drug as to dose and time must vary very much with the peculiarities of the case and the indications at hand.

If the temperature is readily amenable to the remedy, either smaller doses must be given, or at wider intervals. Or, if the patient be a child, or adult enfeebled by long continuance of disease, the same careful discretion must be exercised in its application.

To substantiate the rapidity with which it reduces temperature, and the duration of its effects, the following two charts will be appended. They are of two cases of acute lobar pneumonia, to each of whom one dose of thirty grains of antipyrine was experimentally administered.

Time.	Temp.	Pulse.	Resp.	Time.	Temp.	Pulse.	Resp.
8 A.M.	104.2	104	29	9 A.M.	104.7	122	32
9 A.M.	100.7	84	28	10 A.M.	100.3	98	30
10 A.M.	100.2	86	28	11 A.M.	98.9	92	28
11 A.M.	99.8	82	30	12 M.	98.2	88	28
12 M.	99.3	80	27	1 P.M.	98.8	90	28
1 P.M.	98.6	82	28	2 P.M.	99.3	92	30
2 P.M.	98.8	88	23	3 P.M.	100.2	94	28
3 P.M.	100.2	90	28	4 P.M.	101.8	70	30
4 P.M.	101.1	94	30	5 P.M.	102.6	98	30
6 P.M.	102.8	102	31	6 P.M.	103.5	106	32

It is manifest, after perusing these two charts, that even one dose of antipyrine will reduce the temperature to normal, or nearly so; but, as can be observed, its effect is not very lasting. The pulse-rate was correspondingly lowered with the temperature.

At 8 A.M., with a temperature of 104.2, and a pulse of 104, thirty grains of antipyrine were administered; in one hour the temperature had fallen 3½°, and the pulse had diminished in frequency in about the same ratio. By one o'clock in the afternoon the temperature was normal, that is, five hours after the drug had been given. The temperature then gradually rose, and by six o'clock was 102.4. In the other case, which, by the way, was a woman—the first a man—with a temperature of 104.7,

and a pulse of 110, the same dose was given hypodermatically. In one hour the temperature had sunk to 100, that is, 4.7°, and reached its lowest point at twelve, namely, three hours after its administration. The temperature now gradually and slowly rose to 103.5 by six o'clock.

These two cases illustrate the power the drug possesses even in single doses. They further show how much more rapidly the drug acts when given hypodermatically, though the second case was a female, and perhaps more susceptible to its action.

In our experience a tolerance of the drug has not been observed. In no case has a loss of response to the administration of the remedy been witnessed. But, on the other hand, it is worthy of notice, as has heretofore been mentioned, that some patients respond very markedly on getting the first dose, hence calling for some discretion at the outset of its use.

A most remarkable phenomenon occurs in some cases —the appearance of an eruption. We have noticed it in seven cases—six typhoids and one acute phthisis—three males and four females.

This eruption cannot be looked upon as a result of a prolonged use, or of too liberal employment of the drug, as it did not make its appearance in those cases that received the largest quantities. There seems to be a peculiar disposition at play, just as occurs much less frequently after the use of quinine, as we all know, in which instances the eruption manifests itself unexpectedly, irrespective of the amount used. Nor can we regard it as an expression of intoxication, or of a condition in which the system is, so to speak, saturated with the drug, as in the case of the bromides and iodides; but it can most readily be accounted for by regarding it as a reaction of the nervous system in certain particularly susceptible individuals. That it is not a manifestation of the toxic effects of the remedy is clearly demonstrated by the absence of disturbances of any of the viscera.

The eruption was seen in one case to whom five drachms had been given, in the course of two weeks, in fifteen-grain doses; in the other case, from one to three ounces had been administered in about the same period of time.

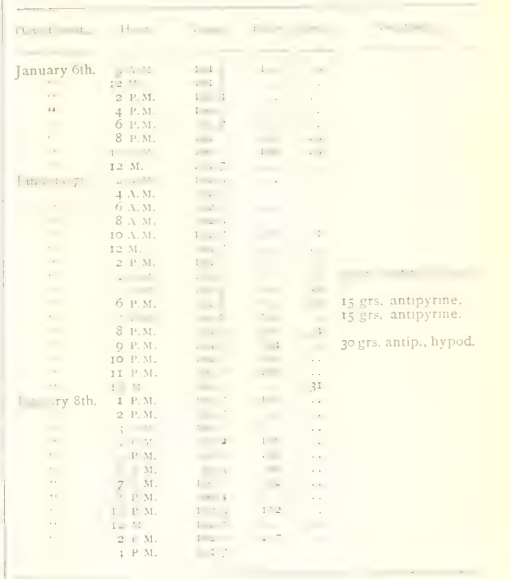
The eruption makes its appearance without any premonitory symptoms. There is no special rise of temperature, no chill, no vomiting, nor any mental disturbances. Furthermore, we have noticed it accidentally in two cases, in which the subjective sensations remained unaltered, and the eruption existed without the patient's knowledge. Sometimes, however, it is accompanied with an intense pruritus.

The eruption occurs principally on the extensor surfaces of the limbs, less on the flexor; it is also seen on the back, and, perhaps, somewhat less abundantly on the chest and abdomen. The neck is seldom covered with the eruption; the face showed in one case a few spots; the mucous membranes were always exempt. It consists of small, reddish, irregularly round spots, resembling, at least in those cases in which the eruption is decidedly pronounced, the eruption of measles. The spots are slightly raised above the surrounding surface, and are about the size of a lentil, or, perhaps, a trifle larger. They are confluent, and the patches formed, being separated by areas of sound skin, present the appearance of a rose marbling, as one writer describes it. On pressure the spots disappear, but leave a light-brown pigmentation.

The eruption disappeared in all cases after eight days, the color becoming more intense for five days, and then gradually fading, notwithstanding the persistence of the use of the drug. In two cases a slight desquamation of the skin took place. A number of writers on antipyrine have described the eruption as resembling that of urticaria. We have failed to have any such cases fall under our observation.

In discussing this comparatively new remedy we have thought that its great advantages as an antipyretic would be more clearly and firmly impressed on the minds of our readers if we should exemplify a few cases and illustrate by charts the effects of the drug in different diseases.

The following chart is of a case of acute lobar pneumonia, occurring in a merchant, aged twenty-eight, of good general physique. He was seen on the second day of his illness, with positive physical and rational signs of an acute lobar pneumonia.



On January 6th, at 9 A.M., the patient was seen for the first time. The temperature was 101½°, pulse 110 and of fair quality. Two grains of ammonium carbonate and one-half ounce of whiskey were ordered every three hours. On the 7th, at 10 A.M., his temperature had risen to 102½°, with pulse of 116, and still of about the same character. The same drugs were continued, without resorting to any antipyretic measures. In the afternoon of the same day his temperature had risen very rapidly to 106½°, the pneumonic process had made great strides, so that the whole of the lower and middle lobes of the right lung were completely consolidated.

It was not until this high degree of febrile movement was reached that recourse was had to antifebrile drugs. Thirty grains of antipyrine were administered hypodermatically. After the lapse of one hour the temperature had sunk over 4°, accompanied by no other discomfort than a moderately profuse perspiration over the whole of the body. At 6 P.M. the temperature began to rise again, and fifteen grains were exhibited by mouth. Notwithstanding the last dose, the temperature kept on rising, and another allowance of fifteen grains was given at 7 P.M., but this also was of no avail, and by nine o'clock the temperature had risen to 104½°. Now thirty grains were again administered hypodermatically, so that ninety grains had been consumed in the course of five hours. It was after receiving this last potion that a rapid lowering of the temperature took place. At 10 P.M. it was 102°, and an hour later 100.7°. During the subsequent four hours the temperature oscillated, and then sunk steadily until five o'clock the next morning, when it was 98½°; that is to say, the normal temperature was reached thirteen hours after the first dose, and eight hours after the last effectual dose had been disposed of.

The subsequent rise of temperature was at first slow,

and then more rapid, but no antipyrine was further required in this case.

The antipyrine had here not only removed the fever, but it had brought about an apyrexia of very considerable duration.

Resolution took place on the sixth day. In this case the temperature might have been more speedily reduced to the normal, had the second and third doses of antipyrine been larger, and had they sooner followed the first.

Hence we see that we were able to keep the temperature twelve hours below 102°, from 10 P.M. on the seventh until 10 A.M. on the eighth, and six hours below 100½°, from 4 A.M. until 10 A.M. on the same day. The pulse-rate corresponded very closely with the oscillations of the temperature, and was very slightly influenced by the antipyrine. The same may be said of the respirations.

The next chart is taken from a case of typhoid fever, occurring in a man aged thirty-seven. It was in the middle of the third week when the temperature reached its highest point.

On September 7th, at three o'clock in the afternoon, when the temperature was 105.8°, the first dose of thirty grains of antipyrine was given, after one hour thirty grains more were given, the temperature having sunk to 104.5° At five o'clock fifteen grains were further administered, the temperature at this hour having been reduced to 101.7°. The patient's body was bedewed with a profuse sweat, otherwise he was feeling quite comfortable. At six o'clock, three hours after the administration of the first dose, his temperature was 99.7°, having sunk over six degrees. It oscillated between this point and 100° until the following morning at eight o'clock.

With the exception of a very marked perspiration, which took place from 4.30 until 5.30, P.M., no secondary effects of the drug were observed. At the time of giving the first allowance of antipyrine the patient was mildly delirious; this delirium was entirely dissipated after the temperature had been reduced to 100°, and thereupon the patient sunk into a quiet sleep.

As will be observed by the above table, the temperature did not reach its former degree of elevation until the lapse of twenty-three hours. The pulse and respirations corresponded very closely with the elevations and depressions of the temperature.

At nine o'clock in the morning, September 9th, the patient again became delirious. Twice, thirty, and once, fifteen, grains of antipyrine were administered at hourly intervals, as on the previous occasion. The temperature at the time of giving the first dose was 104°; in one hour it had sunk to 102°, in two hours to 99.3°, and in five hours to 97°, that is, seven degrees in five hours. As before, there was a gradual disappearance of the delirium as the temperature reached the normal, and there occurred nothing further than a moderately abundant perspiration, lasting for about two hours, and a tendency to sleep, with an indifference as to what was transpiring about the patient. The pulse-rate had been reduced from 132° to 92° per minute, and the respiration rose and sunk with the temperature and pulse.

There occurred no dizziness, no buzzing in the ears, no vomiting, no chill, nor any other untoward or annoying symptom. The accession to temperature was much more rapid in the second than in the first trial, but unaccompanied by any chill or chilly sensations. The original temperature was again arrived at after the lapse of seventeen hours. On the following day a third trial was made, with smaller doses of antipyrine. At twelve o'clock, when the temperature was 104.3°, fifteen grains were given, and two hours later fifteen grains more added. The temperature gradually sunk until a complete apyrexia was established by ten o'clock in the evening, after fifteen hours. Thirty grains of antipyrine were required to reduce the temperature five and one-half degrees in ten hours. The time elapsing until the minimum point of temperature was reached was greater than in the previous trials, and furthermore, the temperature reached its former point of elevation by two o'clock of the same afternoon. This demonstrates that although smaller doses will bring about an entire emancipation from temperature, their effects are not sufficiently lasting.

By way of contrast we made use of sponge-baths and quinine in this case. On the first day, when it was deemed necessary to resort to antipyretic measures, it was found that a sponge-bath had to be given every two hours, for about twenty minutes, to keep the temperature below 105°, and even with this frequent reiteration of the bath, the temperature could not be brought lower than 102°. Half alcohol and half water, at a temperature of 70°, was used in sponging the patient.

The baths were abandoned because of the enervation and exhaustion which followed their repeated use. Quinine was now used in fifteen-grain doses, given every four hours. Two doses were exhibited, one at 10 P.M. and one at 2 A.M. Four hours after the first dose the temperature had sunk one half-degree, and four hours after the second it had been reduced seven-tenths of a degree more, that is, thirty grains of quinine had depressed the temperature 1.2° degree in eight hours. The temperature then rapidly rose beyond its former degree of elevation.

From 2 P.M., September 8th, until the following morning, at nine o'clock, no antipyrine was given, although in the natural course of events the temperature called for it.

The following table is from a case of scarlatina, with diphtheritic exudation on the tonsils and posterior wall of the pharynx.

It was in a girl, thirteen and one-half years of age, who up to the present time had enjoyed good health. She was seen on the third day of her illness, when the diagnosis was still undecided. She complained of general malaise and uneasiness, and some pain on swallowing. The conjunctivæ were congested, and there was a slight coryza, but no eruption. She had had on the same day a decidedly marked chill. At the time of paying her a visit, which was at eight o'clock in the evening of February 12th, the temperature was 104.5°, and pulse 132, rather small and feeble. Half an ounce of whiskey and five minims of the tincture of digitalis were ordered every three hours, and thirty grains of salicylic acid in two doses at hourly intervals. The temperature gradually sunk to 102.2° by the next morning at four o'clock, when it again rose, and oscillated between 104° and 104.5° until four o'clock in the afternoon of the 13th. Now fifteen grains of antipyrine were given, an hour later thirty grains more, and at six o'clock fifteen grains more were administered. At half-past five o'clock vomiting ensued, owing in all probability to the fact that the inhalation of slaked lime with carbolic acid was begun. The fever rapidly disappeared, and by twelve o'clock at night the temperature was 98.2°, so that a reduction of almost six degrees had taken place in the course of eight hours. The patient felt much easier, and expressed a desire for sleep. With the exception of the vomiting at 5.30, and a slight perspiration at seven o'clock, no disagreeable symptoms were manifested. The return of fever was very gradual indeed, the temperature ranged between 98.2° and 100.2° from twelve o'clock at midnight until the next noon. It did not rise to 103.5° until forty-eight hours had elapsed. There was no chill or occurrence of cyanosis while the remedy was exerting its influence. The pulse rose in frequency at first from 108 to 124, and then gradually sunk with the temperature. The character of the pulse changed from a rather feeble to a tolerably strong and full one, which fact may, however, have been not at all ascribable to the antipyrine, but to the whiskey and digitalis. We have been in the habit, in a routine way, unless contraindicated, to use these two drugs—whiskey and digitalis—in conjunction with the antipyrine; not that the heart-action demands them ordinarily, but we believe they facilitate the action of the drug, or rather corroborate its physiological effects, as they both will reduce the temperature to a greater or less extent.

The salicylic acid, which was used at the inception of the treatment, had to be abandoned, because the patient's stomach rebelled. Two more trials with antipyrine had to be made in this case, which are not recorded in the table, before convalescence was entered upon.

This chart is taken from a case of sunstroke. On July 21st, which was one of the hottest days last summer, the temperature being 101° F. in the shade, at three o'clock in the afternoon a call was received to see a man in the country. The patient was a mason by occupation, and had been working since early that morning under the sun's rays, and had consumed about three pints of beer. He had been unconscious for about two hours before he was seen. At four o'clock his temperature was 107.8°, pulse 134, and of very fair quality. His breathing was stertorous, and the face decidedly cyanosed. He was given at once four drachms of whiskey and ten grains of carbonate of ammonia hypodermatically. An ice cap was placed on his head and the body was sponged continuously for one hour with ice-water. The thermometer now recorded a temperature of 108.4°. The antipyrine, for which a messenger had been detailed, now arrived, and thirty grains of the drug were given hypodermatically at once. At the end of one hour the temperature was 107.5°, and forty-five grains of antipyrine were exhibited in the same manner as before.

In one hour's time the temperature was recorded as 103.8°, and fifteen grains more were given hypodermatically, and the temperature thereupon sunk to 100.6° by ten o'clock the same night. The pulse had been lowered in frequency to 112, but it had lost its forcible character, and five grains of carbonate of ammonia, five minims of the tincture of digitalis, and one drachm of whiskey were hourly administered. The temperature now steadily rose until 2 A.M., when it was 105.2°. Thirty grains of antipyrine were now administered hypodermatically. At the end of one hour, the temperature having risen to 105.6°, thirty grains were again exhibited in like manner. By four o'clock the next morning the temperature had been lowered to 103.7°, and fifteen grains of the drug were further ordered to be given. The temperature now slowly sunk to 99.3° by nine o'clock in the morning. The pulse-rate wavered with the temperature, and was at this hour of the day 104, but soft and compressible.

The patient gave the first signs of consciousness at nine o'clock in the evening, and at half-past ten he could easily be roused, and would answer incoherently when spoken to. The temperature oscillated the whole of the 22d between 99° and 102°. It was toward evening of the second day of the disease that his mind became clear, and he was able to give a lucid account of what had transpired on the previous day up to the time of the accident.

A mere glance at this case, with its accompanying chart, seems to us all that is necessary to dispel any sceptic ideas as to the efficacy of antipyrine, and to place it far beyond the reach of any other antipyretic means of the present day. The power evinced by the drug, even in this single case, is sufficient to call forth an unbounded welcome to its discovery, and stamp it as a landmark in the advance of modern medicine.

The next case is one of erysipelas, involving the face and scalp, in a lady, forty-three years of age, who had never before had a similar attack. It was idiopathic in origin, and was seen on the fourth day after its onset.

"	9 A.M.	104.3	128	..	

At 3 P.M., on August 28th, with a temperature of 105°, thirty grains of antipyrine were exhibited; in one hour thirty grains were again given; the temperature then recorded was 103.6°, and an hour later fifteen grains were once again administered, the temperature now being 102.4°. The fever now gradually disappeared, and at 11 P.M. was 99.2°, and it oscillated between this point and 101° during the subsequent five hours. It was in this case, and in this alone, on which we have used antipyrine, that chilly sensations were experienced just before the pyrexia was re-established. In this case it occurred at 4.30 A.M. of the 29th. The temperature had suddenly risen two degrees in one hour, and was preceded by chilly sensations for fifteen to twenty minutes, which were, however, readily amenable to a dose of chloroform and whiskey. The chilly sensations were never repeated in this case, although the drug was administered on several subsequent occasions. Notwithstanding the fact that the lowest point recorded by the thermometer was not normal, still it was practically so, and when we reflect how difficult it sometimes is to make even the slightest impression on the temperature in this affection, our estimation of the remedy as a universal antipyretic is, if anything, raised in our minds. The drug was used in other cases of an analogous character with similarly good results, and without the occurrence of either chills or chilly sensations.

The last chart is of a case of acute pulmonary phthisis, whose course ran with high temperature. On October 3d, at 9.30 A.M., the patient received thirty grains of antipyrine, when the temperature was 103.4°; an hour later fifteen grains more were administered, and then the temperature was recorded every half-hour. The chart shows that the temperature now gradually sunk until the minimum was reached at two o'clock in the afternoon. Five hours elapsed before the lowest temperature was recorded, and then slowly the temperature returned until it had mounted up to 103.5° by half-past six. The temperature curve forms a wave, of which the central point is equally distant from the two ends. Perspiration occurred in this case also, making its appearance an hour after the exhibition of the first dose, and was at its height a half hour, that is, when the second allowance was given. Appended is the chart belonging to this case.

Numerous other charts might be adduced to attest the marvellous powers of this drug as an antipyretic, but in apprehension of making this article still more voluminous we must forego the desire of offering additional testimony. The drug has been largely employed in cases of chronic pulmonary phthisis, attended by high temperatures. It was in this affection that cyanosis occasionally followed from the use of the remedy; and in one case, occurring in the hands of a fellow-colleague, it resulted in a fatal issue—though in this case it is hardly impartial to ascribe dissolution entirely to the antipyrine, as the case was quite far advanced.

In numerous cases of intermittent fever has the drug been resorted to. It shortens the duration of the fever, but it neither prevents the occurrence of high temperature nor of a subsequent chill. More explicitly, if given immediately after a chill, even hypodermatically, it does not prevent the fever from coming on, but it unquestionably moderates it. If administered after the temperature has reached its ultimatum, it hastens its disappearance. In this affection it will never cope with quinine. The same may be said of it in acute articular rheumatism, that it will never vie with salicylic acid. In this latter affection it will reduce the temperature, and thereby relieve many of the concomitant annoying symptoms. In a few cases it seemed to have a beneficial influence upon the affected joints; they became less tender and inflamed, and allowed more freedom of motion.

We have used the drug in inflammations of the serous membrane, in pleurisy, peritonitis, and meningitis, and

have invariably found it capable of reducing the temperature. In one case of puerperal fever it was used with remarkably good results. The temperature ranged in this case between 102° and 106° before the drug was called into use. The fact must, however, not be forgotten, that with the use of the antipyrine more scrupulous measures were adopted in the ablutions of the cavity of the uterus.

The drug has now been tried eighteen months, and the collective results differ materially very little.

Our experience warrants us in coming to the following conclusions:

1. We possess in antipyrine an antipyretic which will reduce temperature most powerfully and rapidly.

2. It is in the great majority of cases perfectly safe; only in very much depreciated states and in delicate children must it be warily given and guarded by cardiac stimulants.

3. It lacks nearly all the disagreeable features which other antipyretic drugs possess. Perspiration occurs in a large proportion of cases, but does not seem to enervate the patients or render them uncomfortable. Pruritus occasionally coexists with the eruption. Vomiting now and then occurs.

4. It may readily be introduced into the system through various channels. Its taste is not particularly disagreeable, and may be easily disguised by some aromatic. Hypodermatically given it acts more decidedly and rapidly, and avoids the possibility of disturbing the stomach. It is unirritating. It may also be given per rectum.

5. It cannot cope with quinine as an antiperiodic or tonic, nor with salicylic acid in acute articular rheumatism.

6. It has practically no influence upon the pulse and respiration. If the pulse be dichrotic, the secondary wave entirely, or nearly, disappears. In other words, it raises the arterial tension.

In conclusion, we would say that very little doubt is entertained but synthetic chemistry will develop many new compounds which may prove of avail at the bedside as antipyretics; but it is our firm conviction that at the present day antipyrine, in sufficiently large doses, is the most powerful, the most certain, and the safest antifebrile drug that we have in our materia medica.

142 East Seventy-fourth Street.

FOUR CASES OF AMPUTATION AT THE HIP-JOINT.

By THEODORE A. McGRAW, M.D.,

Detroit, Mich.

I WISH to put on record four cases of amputation at the hip-joint. All of them took place in Detroit—two at Harper and two at St. Mary's Hospital. In the many changes which have taken place at Harper Hospital, the original notes of the two cases occurring there have been lost, and I am obliged, unfortunately, to report them in part from memory.

CASE I.—Francis S——, aged forty-eight, entered Harper Hospital in March, 1872. He had been under treatment for over five years for a tumor of the right thigh, originating—as I judged from its history—in the soft parts, and gradually implicating the bone. Five times it had already been operated on by different surgeons, and five times it had recurred. On examination I found his whole thigh, from the junction of its upper and middle thirds, involved in a monstrous tumor. He was entirely disabled, and completely bed-ridden. Shortly after his admission into the hospital I amputated the limb at the hip-joint, although I designed, when I began the operation, to make only a high amputation of the thigh. Making large internal and external skin flaps, and cutting the muscles high up by a circular incision, I divided the bone below the trochanters. On examining the bone, after the bleeding vessels had been tied, I found the medulla to be thoroughly diseased, and I therefore proceeded at once to disarticulate and remove the upper fragment, thus changing the amputation into a disarticulation at the hip-joint. The stump healed kindly, and Mr. S—— left the hospital after a sojourn of not more than six weeks. The tumor, a mixed sarcoma, portions of which were myxomatous, contained both round and spindle cells. It had happened that the patient, when twelve years of age, had been injured by the caving in upon him of a bank of earth, and had suffered fracture of the necks of both femora. He had walked ever since with both feet widely everted. The upper fragment of the amputated femur is now in the museum of the Detroit College of Medicine, and shows still the marks of the old injury. On October 17, 1872, the patient returned to the hospital with a local recurrence in the stump. I thereupon cut the flaps entirely off close to the pelvis, leaving a large surface to heal by granulation. Before cicatrization was completed, however, there were evidences of the growth of another tumor in the granulating wound. At his urgent request I operated for the third time, cutting away in this operation some suspicious tissue under Poupart's ligament, and gouging out the acetabulum with a chisel. The operation was completed by the application to the surface of some strong sulphuric acid. He left the hospital on May 15, 1873. It is now nearly thirteen years since the last operation. A short time ago I wrote to his family physician, Dr. Johnson, of Minden, Mich., inquiring as to his fate and present condition. I received in reply the following letter, dated November 5, 1885:

"MY DEAR SIR: Your old patient, Francis S——, is hale and hearty. He has had no local return of the tumor, but there is a suspicious lobulated tumor of the arm (I forget which) of four years' standing, which I advised to let alone unless it should show alarming growth. His general health is good, and he may live yet ten or fifteen years. He does considerable labor in the line of gardening. He has, however, acquired the opium habit, on account of continued pain in the stump."

CASE II.—John S——, aged ten, was taken into Harper Hospital on May 12, 1877, to be treated for a severe burn which he had just received at the iron-works from molten iron. The burn involved the whole of the left thigh except a narrow strip of skin, extending from the crest of the ilium to the middle point of the thigh, and occupying about one-fifth of the circumference of the limb. There were also burns on the leg and abdomen. It was not thought when he entered that he would survive the immediate effects of the injury. He rallied from it, however, and lived five months, during which time every effort was made by transplanting and grafting skin to heal the defect. After five months of unavailing effort, amputation at the hip was determined on as the last resort.

On October 3, 1877, I operated in the presence of the class of the Detroit Medical College. Dr. H. O. Walker controlled the hemorrhage by means of a staff in the rectum, so held as to press on the common iliac artery, and very little blood was lost during the operation.

The only integument available for a flap was that left unburned on the outside of the limb. I accordingly dissected it up to a point just above the trochanter, and gained in this way one long, narrow flap. The femur was then easily disarticulated, and the remaining structures divided by one sweep of the knife. The child rallied well, and bid fair to recover. On the second day, however, he began to complain of stiffness of the jaws, and a tetanus developed, to which he finally succumbed on October 10th, just one week after the amputation. During all this time the wound, though not healed by first intention, looked healthy, and, after the third day, discharged laudable pus.

CASE III.—W. E. L——, of Utica, Mich., aged forty-four, had received during the war a shell-wound of the knee, and had ever since suffered from lameness and stiffness of the joint. In March, 1883, he received a

slight injury on the site of the old wound, and the knee became inflamed again. The consequent swelling never subsided, and the knee and thigh gained steadily in volume; and in March, 1884, his physician, Dr. A. Knight, sent him to St. Mary's Hospital for amputation. On examination I found an enormous tumor, involving nearly the whole thigh and ulcerated at the knee. The patient insisted upon having everything done which might offer hope, and although I had but slight hope of establishing a permanent cure, I proceeded, nevertheless, as a last resort, to amputate at the hip. The operation was performed before the class of the Detroit Medical College, on March 17th, in the following manner: From a point midway between the crest of the ilium and the trochanter, an incision was made to a point on the outer aspect of the thigh, at the junction of its upper and middle thirds. The knife was carried through this cut into the joint, and disarticulation effected, though with great difficulty, on account of the great depth of the joint. The long amputating knife was then made to transfix the thigh from the outer to the inner side, and cut a long anterior flap. A shorter posterior flap was next formed, and the arteries secured. Hemorrhage was controlled in this case by Dr. Boice, by pressure exerted over the arteries by means of a long piece of rubber tubing which was passed in a figure of eight around the thigh and body in such a manner as to cross both the femoral and gluteal arteries. At the moment when the flaps were cut, they were seized in the hand and compressed, thus adding direct digital pressure to that caused by the tubing. The loss of blood was very slight, and the patient rallied from the operation, and recovered with hardly a bad symptom. The tumor proved to be a large, white, round-celled sarcoma. While the tissues were filled with the deposit there were also separate masses, which, when dislodged, looked like great lumps of tallow. The bone, from one end to the other, was completely infiltrated with morbid cells, and its whole structure had become soft and friable. Mr. L—— left the hospital on June 10th, with his wound all but healed. He had begun, however, to cough slightly, although without fever or pain. After his return to Utica the cough became more constant and severe, and it became evident that a secondary deposit had taken place in his lungs. He died on August 10, 1884, nearly five months after the amputation.

Case IV.—William R——, a German, living at Firehaven, aged thirty-seven, entered St. Mary's Hospital on September 15, 1885, suffering from an osteo-sarcoma of the left femur. Eighteen years before he had first noticed a slight soreness of the left knee-joint, arising without apparent cause and unaccompanied by swelling. Ever since then he had experienced occasional pains in the joint, but had never been lame. On April 1, 1885, he noticed for the first time that the knee was swollen, and he dated from that time the beginning of a tumor which developed rapidly in the lower end of the femur. On examination I found a tumor, limited apparently to the lower half of the thigh. In reality, as was proved by subsequent dissection, the whole bone, from the head to the condyles, was involved in the growth, while the soft parts were infiltrated far beyond the apparent disease. The swelling was very sensitive to pressure, and measured twenty-four inches at its greatest circumference. He could bear no weight on the limb, and went on crutches.

In other respects his health seemed to be superb. He was the picture of vigorous manhood, and no symptom indicated trouble with any vital organ. As a matter of routine I directed the examination of his urine. It proved to be of normal quantity, specific gravity, and appearance, and contained no albumen. The microscopical examination was unfortunately neglected.

On September 23, 1885, I amputated at the hip-joint, using every antiseptic precaution, except the spray. The control of hemorrhage was intrusted in this case also to Dr. John Boice, and Dr. H. O. Walker assisted me in the operation, which was performed publicly before the college class.

In this case, as in the last, the rubber tubing was drawn tightly around his thigh and pelvis in a figure of eight. The patient, however, weighed about one hundred and sixty pounds, and was correspondingly difficult to handle. From this cause the rubber tube became displaced during some of the manipulations, and its use was abandoned. Hemorrhage was, however, thoroughly prevented, first of all, by digital pressure over the femoral vessels, and, in the second place, by the instantaneous seizure of the flaps by the hands of the assistant at the very moment when they were cut. His pulse at the close of the operation was even stronger than at the beginning. I operated after the following method:

An external cutaneous flap was first cut by an incision beginning a little below Poupart's ligament, and just inside of the anterior inferior iliac spine, extending in a curve to a point on the outer aspect of the thigh six inches below the summit of the trochanter, and thence to a point a little anterior to and above the gluteal fold. An internal flap of skin was cut to correspond. The muscles inserted into and around the trochanters were then divided and the joint exposed. During these procedures the bleeding vessels were tied as soon as divided. Disarticulation was now effected and the remaining structures divided by one sweep of the knife, the fingers of the assistant following the knife and seizing the cut vessels. The wound was closed with great care, the muscular ends being sewed together with catgut, a drainage-tube inserted into the acetabulum, and the flaps carefully adapted to the underlying structures. Antiseptic dressings were applied with great care, and the patient put to bed with every prospect of recovery. He did well after the operation in every respect but one. During two days his temperature did not rise above normal, but just before his death reached its maximum of 99½° Fahrenheit. On the evening of the 23d nine ounces of urine were drawn by catheter, but after that there was not a drop secreted. He complained of pain in the region of the kidneys, and hot fomentations were applied to relieve it. He died sixty hours after the operation, in full possession of his faculties, apparently of suppression of urine, although there was no uræmic coma.

A post-mortem examination revealed small contracted kidneys which did not seem to be unusually congested. I was gratified to find no trace whatever, in any organ, of a secondary sarcomatous deposit, which, had it existed, might have brought in question the propriety of the operation. As it was, I feel justified in declaring that the operation, if successful as an operation, would probably have added years to the man's life. The disease of the kidneys undoubtedly caused the fatal result, but I do not think that I should have refused to give the patient his one chance of life, by performing the operation, even though I had discovered the kidney trouble in time to consider it as a factor in the prognosis. The examination of the amputated member revealed the same complete involvement of the bone which had attracted my attention in the cases of S—— and L——. The tumor was carefully examined by Professor George Dufield, and proved to be a round-celled sarcoma.

Of these four cases two lived and two died. The two which survived were nearly at the last extremity when operated on—one of these survives to-day, and, I may say truthfully, has gained by the amputation many years of life. All four patients were in a condition which would have given a bad prognosis to any operative procedure, for three of them had been debilitated by long-standing disease, and the fourth was afflicted with the most insidious form of disease of the kidneys. It would not be fair, therefore, to accept such cases as in any way influencing the prognosis of an amputation at the hip in a comparatively healthy subject. This consideration has an especial bearing upon the question of disar-

ticulation at the hip for tumors of the thigh involving the femur.

When a sarcoma springs primarily from the medulla of the bone, or the inner wall of the compact substance, or from the cancellated tissue at either end, it will grow, like all tumors, fastest in the direction of the least resistance, which, in such a case, will be along the medullary canal. I think that I am warranted in saying that such a tumor will infect a bone to its very extremities long before the swelling caused by its growth has become very appreciable. A small sarcoma at the lower end of the femur, therefore, although confined apparently to the condyles, demands amputation at the hip. If an exception were to be made in favor of the giant-celled variety, the so-called myeloid tumor, or if against this dictum may be justly urged the difficulty of diagnosticating the true character of a bony tumor in its earlier stages, the proposition might be modified by confining its application to tumors of very rapid growth, or by providing for an explorative operation to precede that which should be radical. The practice of the profession in dealing with tumors arising in all other bones is to disarticulate at the proximal joint; that it is not so with the femur is shown clearly by the statistics of hip-joint amputations given by Max Schede, as quoted by Erichsen, in which one hundred and fifty-three cases are reported as performed on account of disease. It is evident that the rule of disarticulating at the hip for malignant sarcoma of the femur, if adhered to generally by the profession, would yield more than that number of cases in a single year. There must be some reason for the exceptional avoidance of this operation by surgeons. It may be that these cases are regarded by many as hopeless from the very beginning, and yet that reason for its avoidance could hardly be urged by those who, nevertheless, amputate in the continuity. My first case presented a most hopeless appearance, and the malignant nature of the disease is indicated by its recurrence in the arm after many years, and yet the patient has gained already by the operation thirteen years of life. The last case operated on, although involving the whole thigh-bone and a large part of the soft tissues of the thigh, failed, on post-mortem, to show a single nodule of secondary deposit.

As regards the dangers of the operation in comparatively healthy subjects, I think that it may be overrated by the profession.

The statistics are made up for the most part of cases operated upon in advanced stages of disease. Not one of my four patients can be said to have been in a condition favorable to an operation at the time of operation. Two out of the four nevertheless recovered. The danger from hemorrhage is not great except in very fat, heavy, and at the same time anæmic subjects. The bleeding from the femoral vessels can be readily controlled by a good assistant, who grasps them at the moment of division, and that from the posterior vessels is by no means so excessive as to endanger life before the surgeon can seize and ligate them. One point, however, in operating, I should insist on, namely, that disarticulation should be accomplished before any of the larger vessels are divided. The plan of procedure which I should prefer, with my present experience, would be as follows: The control of the femoral vessels should be intrusted to the unaided hands of a competent assistant, who would follow the knife and grasp them when cut. An external and large flap of integument should be made by an incision extending from Poupart's ligament, outside of the crural nerve, a sufficient distance downward and outward, and curving around the femur to a point a little above the trochanter behind. As the patient lies on his back with extended thigh, the flap should measure an equal distance from either edge (anterior and posterior) to the great trochanter. When this flap is dissected up so that it can be lifted clear of the great trochanter, an inner flap, also of integument, should be made by joining the incisions already made by another, which is carried around the inner aspect of the thigh; the muscles inserted in and around the trochanters are now freely divided, and disarticulation effected. One circular sweep of the knife completes the amputation, and the surgeon, leaving the care of the femorals to his assistant, immediately applies spring forceps to all other bleeding vessels and proceeds to tie them. Should the preliminary incisions be followed by much hemorrhage, the surgeon may tie the vessels injured before proceeding further, and thus make a nearly bloodless operation.

After my experience in this operation, I should certainly discard all abdominal tourniquets, rubber bands, and rectal staffs. It is my belief that the desire of surgeons to display their skill in performing this operation rapidly, and especially in making the flaps first and then disarticulating, is responsible for the great loss of blood which has made it a terror to operators. I can well understand how the necessity of performing a rapid disarticulation at the hip, while bleeding flaps were pouring out quantities of blood, should try the nerves of the most experienced operator. All this can be avoided by the simple expedient of disarticulating first and amputating afterward.

In conclusion, I will say that I hope in the future to learn of a more frequent performance of this operation for malignant tumors of the thigh in their early stages. The general rule applied to cancerous and sarcomatous tumors of other bones, of removing the whole affected bone, should be relentlessly applied to the femur also; and I feel confident that the statistics of the operation, if performed, not as a forlorn hope, but as a hopeful and early effort to save life, would soon cause it to rank among the favorite operations of practical surgeons.

ELEVEN CASES OF PHTHISIS TREATED BY INTRA-PULMONARY INJECTIONS OF CARBOLIZED IODINE.[1]

By JOHN BLAKE WHITE, M.D.,

PHYSICIAN [illegible] OF THE NEW [illegible]

In a treatise upon "Phthisis Pulmonalis," by J. Hughes Bennett, the author remarks: "I confidently look to the future as affording means for demonstrating the ratio and conditions under which the prognosis of phthisis may be determined. In the meantime, I can only express my conviction that its permanent arrestment and cure are, by judicious treatment and hygienic management, becoming every day more frequent and more widely extended."

Assuring remarks like these from a man of such recognized skill and experience cannot fail to encourage the profession at large to renewed efforts to check this greatest outlet of human life.

Physicians have tested, over and over again, the merits of sprays and of inhalations of vaporous solutions. Astringent fluids, as well as other fluids, have been injected down the larynx and into the bronchi for the cure of phthisis. Actual openings of the pulmonary cavities from without have been practised, and every effort made to cause them to cicatrize: but the results have been unpropitious. I feel confident, however, that some such plan of surgical treatment, with strict attention to the principles of antisepsis, as practised at the present time in cases of abdominal section, can be made quite as successful and warrantable a procedure in these cases.

The curability of phthisis, in its several stages, is becoming quite as established as the fact that the disease is, in this country, one of progressive mortality.

Post-mortem examinations frequently demonstrate that the disease has been checked, not only by medical skill, but sometimes by natural effort. The more we study the nature and progress of consumption, the more do we be-

[1] Read before the [illegible] Medical [illegible]

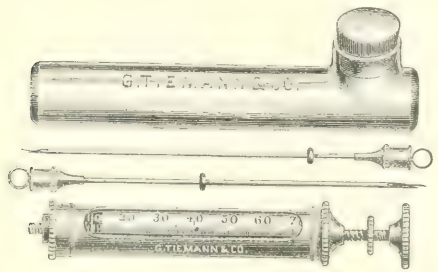
come convinced that local medication must enter largely into its successful treatment.

Actual injections into pulmonary cavities through the intercostal spaces have been practised within a very recent period, with some supposed benefit, and the procedure appeared to me so very rational a plan of treatment that I determined to make a judicious trial of it during my service at Charity Hospital, where a large number of cases were aggregated. The local application of remedies which possess and exert alterative influences seems to promise the most reliable means of ridding the system of the tubercular material, either by disappointing its development or by rendering it capable of absorption or excretion.

This process would, of course, be more or less active in proportion to the patient's physical condition, which would be maintained by an arrest of the local destructive conditions present in the lungs.

The successful treatment of phthisis would include every means, local and general, for checking the accumulation of the tubercular exudation and arresting ulcerative processes, for the system suffers, of course, in proportion to the extent and continuance of suppuration, if not from the actual absorption of the products of ulceration. We observe every day, in the wards of our large hospitals, many patients who, in consequence of a low state of vitality, manifest dangerous tendencies to suppurative disturbances after accidents. The injured tissues decay, and indolent ulcers appear which require lotions or ointments of a stimulating character to induce healing action. The walls of pulmonary cavities are similar to those of indolent ulcers on the external parts in the continuous molecular disintegration of contiguous tissue, and require, it seems reasonable to suppose, direct local treatment. Specialists in every branch of medicine appreciate the value of, and practise local medication in addition to, the general treatment of the patient.

In view of all these facts, I ventured to treat a few cases of phthisis by the careful introduction of a few minims of carbolized iodine into the pulmonary excavations, through the intercostal spaces, by means of a small syringe and needle which I had made for the purpose by George Tiemann & Co. The case consists of a graduated



metallic and glass syringe large enough to hold one drachm of fluid, a wide-necked reservoir for holding the solution to be used, and two needles, four inches in length, made of well-tempered steel, of the calibre of a small-sized aspirating needle.

At the extremity for the escape of the fluid are three or four apertures arranged circularly, which permit the injection to enter the pulmonary cavity in the form of spray. Along the shaft of the needle is arranged a movable guard of hard rubber, which is used to regulate the depth to which it is desired to insert the needle into the lung, in order to reach the cavity which is the subject of treatment.

The depth of the cavity and its location can be determined, by auscultation and percussion, with accuracy, which is a proceeding requiring due study and skill.

By this plan of treatment the most urgent symptoms were in all of the cases relieved so long as the treatment was continued. In two aggravated cases, though the symptoms which distressed the patients most were ameliorated and life apparently prolonged, they nevertheless succumbed to asthenia a few weeks after treatment was discontinued.

The distressing cough always present in these cases was markedly controlled, and the expectoration, which in some of the cases was excessive, was diminished materially by the injections. The patients' general health in some of the cases seemed to have decidedly improved. This was especially observed in Case II., where expectoration one week after the first injection was reduced from ten ounces to one ounce in twenty-four hours, and in Case XI. from sixteen ounces to two ounces in the same period.

The prognosis seemed so unfavorable in Case II., when I began service at the hospital in November, 1885, that I rather hesitated to subject him to the treatment. Nevertheless, he revived so much after the first and second injections, that when I last saw him, in January, 1886, two months after I instituted the treatment, he appeared in every respect much improved in health and strength.

This case seemed especially unpromising of good results from treatment, as he had a very large excavation in the right (upper portion) lung, and a small excavation enlarging in the left apex, and though in every respect seriously ill, nevertheless responded immediately to treatment in the most satisfactory manner.

A paroxysm of coughing followed the injections in almost all the cases, but in a few minutes ceased, and for two or three days after, the coughing was less frequent and the expectoration diminished. The night-sweats, which were quite profuse in some of the cases, seemed to be decidedly modified by the treatment. I had the pleasure and satisfaction of having had my diagnosis, in the first few cases, verified by Dr. James R. Leaming and my father, Dr. O. A. White, who visited the hospital with me on December 8, 1885, and on a subsequent occasion by Dr. J. L. Morrill, of this city.

In Case II., Dr. Leaming stated, after auscultation of the chest, that the cavity in the right lung had "hardened walls," which was not the condition prior to the intrajection of carbolized iodine, and affords a valuable instance of the benefit following this plan of treating phthisis. I am indebted to Dr. William Moore, House Physician, Charity Hospital, for a record of the cases treated and carefully taken notes of the progress of the patients under treatment.

Case I.—D——, male, aged forty-three. A large cavity at right apex, with flabby edges and loud, moist, gurgling rattles. Patient's general condition fair, though manifestly emaciated; appetite fair. Some dulness obtained over left apex.

First intrajection practised November 31, 1885, followed immediately by very little coughing. Tasted the iodine. Between forty-eight and seventy-two hours after the operation the coughing was less frequent and the expectoration diminished. The pain which he felt prior to the operation over the region of the cavity was also ameliorated. Four hours after first intrajection the temperature was 100.4°, ten hours after, 99.6°, and twenty hours after, normal.

Second injection, given December 5th, was followed by a severe paroxysm of coughing, which continued for about fifteen minutes, with frothy fibrinous expectoration. Complained of pain at the point of puncture for some hours after the operation. Cough and expectoration controlled.

Third injection performed December 8th, in the pres ence of Drs. Leaming and O. A. White. Coughing and expectoration of frothy fibrinous character followed immediately after the operation, but both ceased in a few minutes. The patient's general condition between the

second and third days after was much improved, and the temperature never exceeded 99.6°.

Case II.—S——, male, aged forty-seven. A large pulmonary excavation was discovered on examination at the upper portion of the right lung, extending down to third intercostal space. There was also dulness on percussion over the left apex, and a small cavity diagnosed in this region. The patient was weak and emaciated. Night-sweats profuse and exhausting. Loud, moist, gurgling rattles over upper portion of right lung heard anteriorly and posteriorly. Expectoration was quite abundant, and cough distressing and frequent.

First injection, given November 28th, was followed by very slight pain, and a short paroxysm of coughing, with a frothy fibrinous expectoration, which ceased in about ten or fifteen minutes. Almost immediately after the injection the patient tasted the iodine and carbolic acid.

Second injection was administered December 1st, after an attempt was made to aspirate the right cavity, with the hope of removing some of the large amount of the exudation which was present. Although a good-sized aspirating needle was introduced into the cavity, none of the pus was withdrawn, which was due, doubtless, to the very viscid and tenacious character of the fluid contents of the cavity.

About fifteen minims of the carbolized iodine were then introduced into the cavity. A violent paroxysm of coughing was occasioned, followed by frothy fibrinous expectoration. Between forty-eight and seventy-two hours after there was so much pain complained of, which he described as *burning* in character, that a morphine hypodermic was administered. This soon gave relief, after which the cough and expectoration were lessened, and the patient declared himself feeling generally much better. After the first intrajection there was a slight rise in temperature, within twenty four hours not more than .4° to .6° above normal, to which latter degree it gradually fell within a short period. The temperature was not materially affected after the second intrajection.

On December 8th the patient's general condition was quite satisfactory. Coughed less frequently. Expectoration reduced from ten ounces to one ounce in twenty-four hours, and the facial expression less pinched and anxious than it was prior to the commencement of the treatment. Upon auscultation the moist sounds were found decidedly modified, and the walls of the cavity gave every indication of a more dry or hardened condition, suggesting an attempt at cicatrization. I desired to repeat the treatment, but the patient's recollection of the pain following the last operation caused him to oppose any interference at present. I do not think there is any doubt but that the pain he experienced after the last intrajection was due more to the insertion of the large aspirating needle than the injection of the carbolized iodine. No such irritability occurred after the first injection, nor was the same amount of pain occasioned in any of the other cases treated with the same injection.

I had an opportunity of seeing this patient in the month of January, when his condition seemed so much improved that I could not but think that, had he permitted a continuance of the treatment, a positive cure might have resulted. I am, nevertheless, impressed with a conviction that his life has been most certainly prolonged by this treatment, due to the arrestment, or perhaps I should say modification, of the destructive process in the lung.

Case III.—M——, male, aged forty-nine. A large cavity under second intercostal space, left lung. Small cavity also at right apex. Patient's general condition fair. Cough and expectoration symptomatic. Night-sweats profuse and debilitating.

First intrajection, given November 28th, was followed by very little pain. Absolutely no paroxysm of coughing, and no expectoration resulted. Did not taste the injected fluid. Between forty-eight and seventy-two hours after, the symptomatic cough was less frequent, and the mucopurulent expectoration was diminished one-third. Six hours after the operation the temperature was 100.6°, and twelve hours after it was normal.

Second injection, given December 1st, was followed by slight pain and some cough, with moderate expectoration. Tasted the carbolic acid. Forty-eight to seventy-two hours after the operation the expectoration continued to be less in quantity and the cough harsher. The night-sweats entirely checked.

Third injection was given December 22d, and produced prolonged coughing, with frothy fibrinous expectoration, which continued for twelve hours. Tasted the injected fluid and complained of heat in the part of the lung injected. A regular rise of temperature for three successive afternoons was noted, varying from .5° to 1.5°, due, undoubtedly, to some special influence other than the treatment.

Case IV.—B——, female, aged twenty-two. When admitted to the hospital this patient was greatly emaciated. Both lungs excavated, though the left organ manifested a greater degree of decay. Night-sweats profuse. Cough and expectoration were urgent.

First injection, given December 8th, was followed by considerable pain and prolonged coughing. Patient was slightly hysterical for a short period. Forty-eight to seventy-two hours after operation no marked change in the cough or expectoration was observed. The taste of the injected fluid was still present. Twenty-four hours after the injection the temperature varied from 100° to 101.4° for subsequent four days.

It was not deemed advisable to repeat the pulmonary injections on account of the debility of the patient. She died January 8, 1886.

Case V.—H——, female, aged forty. Small cavity at right apex. Expectoration abundant. Night-sweats urgent. Patient's general condition fair.

First injection, given December 11th, produced little pain, no cough or expectoration; patient tasted fluid injected. Between forty-eight and seventy-two hours after, the patient declared she felt much better than before the operation, and her cough and usual expectoration decreased. Six hours after the temperature was 99.8, but gradually fell to normal within twelve hours.

Second injection administered December 22d. Felt some pain in posterior aspect of lung corresponding to point of injection anteriorly. Some cough followed, with slight fibrinous expectoration. Between forty-eight and seventy-two hours after, the pain in back of chest ceased, and she continued, in her own words, to "feel better." The temperature, about twenty-four hours after injection, was 98.5.°

Case VI.—C——, female, aged twenty-five; patient greatly emaciated; cavities found in both lungs—upper portions; expectoration not excessive, but always tinged with fibrine; complains of pain in both lungs. First injection administered December 11th. Was followed by slight pain; no paroxysmal coughing, but ordinary cough resulted in slightly blood-stained expectoration. Did not taste the injected fluid. Between forty-eight and seventy-two hours after, the pain in the lung disappeared. There was no variation in temperature other than a rise of from .4° to .6° every afternoon. As this patient became insane, the treatment was not continued, and on January 1, 1886, she was transferred to the city asylum. Symptoms of mania were apparent before the treatment was commenced.

Case VII.—D——, male, aged forty-eight. A large cavity was discovered in the upper part of right lung, and a small excavation at the apex of left lung. Excavating process was rapidly extending. Emaciation marked and rapid, with anorexia and profuse night-sweats. First injection administered December 12th, followed by no cough nor other result than taste of the injected fluid. Forty-eight hours after the operation his usual coughing was rendered less urgent. Expectoration

was not affected. There was no rise in temperature above 99° up to time of the second injection, December 18th, after which the expectoration was lessened, and the patient declared himself better. Third injection was given December 22d, and was followed by pain and prolonged coughing, with fibrinous expectoration, which ceased in due time, and the patient's condition was subsequently improved.

Case VIII.—S——, male, aged thirty-seven. A small cavity was found at right apex, and dulness on percussion over left apex. Emaciation not pronounced. Expectoration excessive. An injection was administered December 18th, which caused only a slight amount of coughing and clear expectoration. Forty-eight hours after, cough and expectoration slightly modified; complained of some pain at the point of injection on respiration. Temperature not above 98.5°.

Case IX.—S——, female, aged thirty-one. Both lungs excavated; the right more extensively. Patient very anæmic, and much exhausted from repeated pulmonary hemorrhages. Night-sweats profuse; cough distressing; expectoration abundant. Right lung injected December 15th. Trifling pain followed, with no paroxysmal cough and no expectoration. Had some pain posteriorly in chest, corresponding to anterior part of the lung injected. This pain ameliorated between forty-eight and seventy-two hours after the administration of the injection. Cough less urgent, but amount of expectoration about the same. Temperature not affected. Second injection was administered December 25th, and was followed by much pain and a hemorrhage. Patient manifested symptoms of shock, requiring stimulants. During subsequent three days the patient was semi-delirious and pulse continued feeble. On the fourth day mental integrity was restored, but patient seemed quite feeble. Temperature twenty-four hours after injection was 97.8°, and respirations were 40. On the fourth day the temperature was 98.8° and respirations 22. As I left the service January 1st, the treatment was not continued. This patient died January 25, 1886.

Case X.—G——, male, aged thirty-six. A very large cavity was made out at right apex, and one almost equally as large in upper part of left lung. Sweats profuse; cough and expectoration urgent.

First injection was administered December 15th, which was followed by some pain and slight coughing without expectoration. The paroxysm of cough did not continue long. Three days later the patient was much better. Expectoration and cough remained the same as before the operation. No noticeable change in temperature took place.

Second injection was given December 22d, after which a paroxysm of coughing ensued with some bloody expectoration. From the second day after, the expectoration was perceptibly diminished. There was no change in the temperature, and the patient continued better up to the termination of my service, January 1, 1886.

Case XI.—May 1, 1886, I was invited by Dr. Ira B. Read to see in consultation with him Mrs. K——, aged forty-five, married, who has been the subject of phthisis for several years. All of the symptoms of consumption were pronounced. Night-sweats profuse and debilitating. Cough urgent, and expectoration excessive, amounting to a pint in twenty-four hours, and wholly puriform and fetid in character. A large excavation, elongated, was distinctly made out, extending from the apex of left lung down to fifth intercostal space, at which point loud, gurgling rattles were heard. There was manifest flattening of the left chest. In the presence of Drs. Read and J. L. Morrill I introduced twenty minims of carbolized iodine into the upper part of the cavity through the second left intercostal space. The operation was followed by no paroxysm of cough, nor was there any expectoration, and no pain or irritation whatever was complained of. May 5th, the following was received from Dr. Read: "Our patient is doing well; she has coughed but very little, and raised but little; she has not sweated any for two nights; she feels very hopeful, and does not dread our visit next Saturday. I sincerely wish she may be permanently benefited. I will get a full history of her case for you," etc. I quote Dr. Read's own words, that the very satisfactory character of the report may not be attributed to my enthusiasm and confidence in the treatment. May 8th and 13th, cavity injected with thirty minims of carbolized iodine, and excited no cough nor pain. No expectoration followed the injection up to the time we left the house. The patient manifested (May 13th) decided improvement in her general health. Had no night-sweats since May 8th. Cough less frequent, and expectoration much modified in quantity and quality. Her appetite has greatly improved. Has fancied and eaten meat. Has been out to walk every good day, and felt less fatigue than before the treatment was instituted.

As to the ultimate benefit likely to result from this method of treating phthisis, little can be judged from the limited experience thus far adduced. I cannot but feel, however, that the treatment is an eminently rational one and promises good results, especially in a more favorable class of cases. I take great pleasure in reporting these cases, hoping that they will afford interest and encourage others to study and experiment in the same direction.

When the treatment was first instituted, in November, none of the patients treated during this month manifested as much effect from shock after the injections as in December.

This I attributed to the fact that there was a decided difference in the temperature of the fluid used, and suggested the advisability of always warming the fluid to be injected up to the degree of the body temperature. The patient should be fortified with a stimulant before proceeding, and I have thought that sometimes the operation might better be preceded by a hypodermic of one-eighth ($\frac{1}{8}$) of a grain of morphia, with a hundred and twentieth ($\frac{1}{120}$) of a grain of atropia. Should this be done, of course, anodynes should be omitted from the fluid injected.

I advise this plan in preference to including these remedies in the intra-pulmonary injections, as it lessens the probability of shock, although I have sometimes included them, and with good results.

Dr. Gougenheim, of Paris, reported in *The British Medical Journal* the result of intraparenchymatous injections of bichloride of mercury ($\frac{1}{2000}$, $\frac{1}{1000}$, and $\frac{1}{500}$) in thirty-three cases of phthisis. Immediate improvement was observed in twenty-one of the patients thus treated, and only ten out of the whole number died. No muscular, pleural, or pulmonary lesions were found, at the necropsies of those treated, which could be attributed to the injections. This bears out my own experience in these particulars. Dr. Beverley Robinson, of New York, also reported cases treated in this manner, with benefit, using injections of dilute Lugol's solution. His article upon this subject (The Medical Record, January 10, 1885), as well as that of Dr. Pepper (*American Journal of the Medical Sciences*, October, 1874), are most valuable contributions to the treatment of phthisis by this method.

To patients afflicted with this justly dreaded affection the intra-pulmonary treatment opens up new hope, and, I think, with good reason. The plan of treatment enables the physician no longer to stand with folded arms awaiting for his patient the inevitable end, but puts in his hands the means of prolonging, and sometimes of saving, life.

The following formula is the one which I have been using, and which seemed to occasion the least amount of irritability when injected:

℞. Atropia..... gr. $\frac{1}{3}$.
Morph. sulph..... gr. ii.
Tinct. iodine..... ʒ iij.
Acid. carbol. (pure)..... gtt. xx.
Glycerine..... ʒ iss.
Diluted alcohol, 20 to 30 per cent. ʒ iss.
M. Sig.—15 to 30 minims.

Clinical Department.

CASES IN OBSTETRIC PRACTICE—RESUSCITATION OF CHILD DELIVERED AFTER CORD HAD CEASED PULSATING—PECULIAR POSITION OF PLACENTA AS A CAUSE OF TEDIOUS LABOR.

Dr. William B. Lyman, of Wilson, Wis., sends the following instructive reports:

Case I.—Was called to attend Mrs. L——, in her third confinement, a distance of twelve miles from my office, and after a rapid drive arrived to find her in labor, having had pains for several hours. A digital examination revealed the os uteri fully dilated, the "bag of waters" yet unbroken, and a soft gelatinous mass presenting, together with a foot or hand, which I was then unable to determine. After several unsuccessful efforts to change the position of the child by bi-polar version, and concluding the presentation to be transverse from the condition already reported, together with the extreme lateral diameter of the uterus, I informed the father of the necessity for turning, and also that I could promise nothing as to the viability of the child when born, but thought it would probably be dead, anticipating in this prognosis the prolapsus of the funis, which occurred, and feeling that it would be impossible to deliver rapidly enough to save the child. After rupturing the membranes I found the cord extending about three or four inches external to the labia, and a hand and foot presenting, which proved to be the right hand of the child and the left foot, the head resting in the right iliac region. Owing to firm contraction of the uterus, I was unable to introduce my hand, for the purpose of podalic version, for some moments, but finally succeeded, and in the effort to deliver the child rapidly, by withdrawing it by the foot, the arm engaged with the head in the superior strait. At this time I felt the cord and found no pulsation, and it felt cold. I attracted the attention of the nurse to this fact, and remarked it was useless to hope for a living child. I then dislodged the arm from beside the head after several minutes of continued effort, and delivered. The cord was still pulseless, and there was no appearance of life in the child; but I wished to leave nothing undone, and so made efforts at resuscitation. After several minutes—possibly three—the first effort to gasp was seen, and breathing at intervals of fifteen or twenty seconds for several minutes. The child finally revived, and is now a bright little one of several months.

I regard this as a peculiar case from the fact of at least five minutes intervening from the time pulsation ceased in the cord to the time of nature's first effort to relieve the asphyxiated new-born, and think, after this experience, I will never lay a new-born babe aside until having used every effort at resuscitation, even though the case seems entirely hopeless.

Case II.—Called to see Mrs. D——; found her having slow but persistent dilating pains, os dilated about the size of a silver twenty-five cent piece, but thick and rigid, apparently not at full time. I gave anodynes, and in the morning left the patient comfortable. In a week I was called again, found patient had suffered same pains during pretty much the whole week. The os was dilated a little more than before, pains continued at regular intervals for twenty-four hours, during which time I remained with her. The os being still undilated, I observed that pains, although making the os rigid, failed to cause the bag of waters to make pressure against it and thus mechanically distend it. Pains were hard, and I concluded, although I had never read of similar cases, that the placental attachment was directly in the fundus of the uterus, and the membranes were too short to allow the "bag" to reach the os, especially as it became tense and fully distended with each pain.

Contrary to all teaching, I ruptured the membranes at this time, and the head descended, making pressure against the os, rapidly dilating it, and labor was normal from this time. After labor, found the opening in sac directly opposite placenta, showing my judgment to have been correct as to the location of placenta and probable cause of the tedious labor. What is the opinion of the profession as to this cause of tedious labor?

Progress of Medical Science.

Spasm with Spinal Motor Mechanisms.—In Dr. Sharkey's third Gulstonian lecture he considered the subject of spasm in connection with spinal motor mechanisms. He divided the subject into three parts, viz., 1, spasm produced by diseases of efferent spinal nerves; 2, spasm produced in a reflex manner by diseases of afferent nerves; 3, spasm produced by diseases of the ganglionic cells. Dr. Sharkey said that a large proportion of cases classed under 1 were not to be explained on the assumption that the diseased nerve caused excessive muscular contraction. The real fact was that the healthy muscles were those actively concerned, and produced contractures because the diseased muscles were passive, atrophied, and could not oppose them. Tetanus he regarded as perhaps an exception, but its pathology could scarcely be said to be known, and he had failed to make out any changes in the motor nerves. Even in regard to 2, Dr. Sharkey maintained that many cases are accepted as of reflex origin, which at any rate carry little conviction with them. Many cases occur where some sensory nerve is the seat of severe pain, or where a part is diseased which it is painful to move. A good example of the former class was furnished by facial muscular spasm accompanying facial neuralgia; and of the latter, rigidity in joint disease. But the most ordinary way of expressing pain was by some overaction of the facial muscles, and the ordinary way of preventing pain in joint disease was by keeping the joint still and opposing attempts at movement. Reflex spasm produced by disease of afferent nerves could therefore scarcely be dealt with apart from spasm produced by disease of ganglionic cells (3), for it was questionable how far stimuli applied to afferent nerves in chronic disease would produce muscular spasm if the centres were healthy. Reflex spasm no doubt did occur, but how frequently it did so, or how far the afferent or efferent nerves, or the nerve-centres, take the leading part in its production, were points which could scarcely be estimated. Dr. Sharkey supported Charcot's view, that various affections of joints may give rise to rigidity of muscles in a reflex way, and related a case in support of this opinion. He also gave an account of a case in which rhythmical contraction of the palmaris longus muscle occurred (ninety times a minute) after an injury and became permanent. Another case he brought forward was one of spasmodic movements of the jaw and of the floor of the mouth, due to injury.

The Relation of the Chorda Tympani to the Sense of Taste.—Dr. E. Schulte relates a case in which the chorda tympani nerve was divided in an operation on the left tympanic cavity. There followed immediately paralysis of taste in the anterior two-thirds of the left side of the tongue, and even after eight weeks there still remained complete absence of the perception of taste for sweet, sour, bitter, and salty substances. The temperature sense was intact, but the patient was unable to tell whether the hot or cold substance was a solid body or a fluid. The senses of touch and of pain perception were unaffected. From a study of this case the author came to the conclusion, as opposed to the opinion of Carl and Wolf, that the chorda tympani contained all the fibres of taste perception for the anterior two-thirds of the tongue.—*Centralblatt für klinische Medicin*, April 3, 1886.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, May 22, 1886.

"INFLUENCE OF SEX IN DISEASE."[1]

IN bearing the burden of disease under which humanity groans, the members of one sex oftentimes think that they have more of it than the other. Mr. W. Rogers Williams, the Surgical Registrar to the Middlesex Hospital, gives us a view of how matters stand in England in this respect. He bases this upon an analysis made of hospital cases, which consisted of 32,509 males and 28,175 females, and the mortality returns derived from the Registrar-General's reports for twenty-five years, from 1848 to 1872, which includes the enormous number of 5,419,865 males and 5,082,281 females. With this vast mass of humanity to deal with, one can believe that conclusions might be arrived at which would command respect.

As a general thing women think they fall heir to more of the ills of the flesh than men. They will feel more cheerful, since misery likes company, when they learn that "men are more than twice as subject to carbuncles as women." Perhaps it is for this reason that as a popular standard of measurement for pain "the boil" has been taken, and we have the proverbial statement "as sore as a boil." It is doubtful if there has been a thorough realization of how appropriate to his sex was the disease from which Job suffered so much.

Our writer, contrary to what has been adduced by other less careful investigators of the subject, shows that men are more liable to small-pox, measles, scarlet fever, and febricula.

Typhoid fever attacks both sexes alike, but women die more frequently than men, while the reverse is true of typhus.

Diphtheria, whooping-cough, and influenza are decidedly more frequent in women than in men, while men in their turn suffer more from gout. In fact, gout is almost entirely a masculine disease. We are told that in the degenerate days of the Roman Empire this was not so, for women then rivalled the men in all kinds of intemperance. Women need to take warning, since gout is increasing among them.

Men are more liable to tetanus and hydrophobia—five times as liable as women—and also more liable to locomotor ataxy. Both have an equal tendency to epilepsy, while chorea, insanity, and hystero-epilepsy are more often feminine than masculine. One sees a growing tendency to credit men with some hysteria. The unfortunate name of this disease has prevented a proper understanding of its distribution among the sexes.

Briquet, in 1,000 cases, makes the proportion of 1 male to 29 females affected by it, while our author gives the ratio as 1 to 16.

The universal fear of cancer which haunts women is not without foundation, for they are twice as liable to these neoplasms as men, and are much more prone to growths which are benignant.

[1] The Influence of Sex in Disease. By W. Rogers Williams, F.R.C.S. Published by J. & A. Churchill. London, 1885.

A NEW ERA IN MICROSCOPICAL WORK.

UNDER this head Dr. Frank L. James, a St. Louis microscopist of high standing, describes (*St. Louis Medical and Surgical Journal*) the new optical glass discovered by Abbé and manufactured by Zeiss. Dr. Van Heurck, of Anvers, communicates to the *Journal de Micrographie* the results of his trials with the new lenses. He says:

"The objective is homogeneous immersion, of a foca distance of 3 mm., or about one-eighth inch English measurement. It is not arranged for cover-glass correction, as this is not necessary, that function being attained by means of the sliding tube of the body. It contains five lenses, and has a numerical aperture of 1.4, which is a trifle less than has been obtained in England and America (1.5); but so far as its optical qualities are concerned it is far superior to anything ever before made, the new glass permitting the absolute correction of all aberrations. The field is perfectly flat, the minutest object in the extreme edge of the field showing as sharply and clearly as though it were in the exact centre. With the vertical illuminator an amphipleura (silvered) is resolved into pearls—not merely in spots, but over the entire frustule, and with such clearness that these pearls can be counted. In the study of other diatoms I have found details which have hitherto escaped notice. As to the bacteria, details of structure are shown that have never before been seen—details that will without doubt serve to differentiate them by ocular means. Accompanying the objective are three eye-pieces, two for direct use and one for photography. They are also made of the new glass and by entirely new optical formulæ."

Dr. James does not appear to have used or seen these new objectives, but he is confident of their great utility. We should judge from descriptions so far given that the great advantage secured by the new lenses is through the eye-pieces, which enlarge the image without causing a loss in definition or illumination.

A NEW DIAGNOSTIC TEST FOR TYPHOID FEVER.

STATISTICS regarding the therapeutics of typhoid fever are almost always seriously vitiated by doubts as to diagnosis. This is more especially the case with the alleged abortions of typhoid. It is very desirable, therefore, to have some definite test of the presence or absence of the disease in its early stages. The temperature curve is known to be often far from typical, the roseola does not appear, if at all, until from seven to twelve days; there are, in fine, no pathognomonic symptoms in the earlier stage of the disease.

Several observers have recently tried to establish a

method of making the typhoid bacillus of Eberth a means of positive diagnosis. This bacillus is now quite generally conceded to be a constant accompaniment of the disease in question, and of no other.

Attempts to find this bacillus in the blood have not been very successful, although Neuhaus (*Berlin. klin. Wochen.*, 1886. No. 6) observed them in blood taken from incisions made near the roseola spots. M. Bouchard has also found the bacillus in the urine. Recently Philopowicz (*Wien. med. Blatt*, 1886, Nos. 6 and 7) (*L'Union Médicale*) has communicated the results of his personal experience in the examination of blood drawn from the spleen of typhoid patients. Having washed the skin with a solution of bichloride, 1 to 1,000, he inserted the needle of a hypodermic syringe, previously sterilized, between the ninth and tenth ribs, and withdrew some of the splenic blood and juice. In this he was able to recognize the bacilli of Eberth, and produced cultivations showing their specific character. All this was done in four patients, before the appearance of any roseola. There does not seem to be any great inherent difficulty in using this method of testing the nature of a suspected fever, provided, of course, that subsequent experience confirms the results of Philopowicz. Such a method cannot be made a routine one, but in hospitals it may be frequently used, and by it perhaps the much-disputed question as to whether typhoid fever is ever aborted can be settled.

In this connection we would call attention to the daring experiments of M. Payon (*L'Union Médicale*, No. 115, 1885), who inoculated pure and attenuated cultures of the typhoid bacillus upon himself and five other persons, without producing any definite symptoms of typhoid fever as it occurs in man.

THE IRRIGATION TREATMENT OF CATARRHAL JAUNDICE.

A RECENT number of one of the Berlin journals reports the revival of this method of treatment, originally proposed by Krull in 1877. He reported a series of eleven cases, and Loewenthal, who has lately reintroduced the plan, reports forty-one. The method is, in brief, the irrigation of the lower bowel by cold water once in twenty-four hours. It is claimed that the whole duration of the disease is shortened, that the gastro-hepatic symptoms speedily pass away, and that the headache soon ceases. The appetite very quickly becomes restored, and the patient is free from that peculiar lassitude so generally accompanying jaundice.

In the actual application of the method the following details are to be observed: For each injection one or two litres of water are to be used, with a temperature at first of about 12° C., and rising each day about 3° C. For children one single litre suffices. The average number of irrigations found necessary in the cases alluded to was four. In all an evacuation followed the first washing. In some diarrhœa ensued, but was checked by the subsequent washings at a higher temperature. By the third injection the passages generally have a yellow or brownish color. At the same time the yellow color fades from the skin and the bile-pigment leaves the urine.

The method has, at least, simplicity to recommend it, though it is hard to see just how it acts. As one of our exchanges suggests, the irrigation of the stomach (as suggested by Kussmaul and Senator for intestinal strangulation) with plain or medicated water would doubtless be of value. It would, at least, act directly on the inflamed mucous membrane of the stomach, which suffers in severe forms of the disease.

THE WORTHLESSNESS OF QUININE IN CONTINUED FEVER.

NOT often does a prophet and a poet arise among us able to denounce our errors with rugged, Baptistic vigor, and to set our faces again toward the sunlight of medical truth. Such a prophet, however, has spoken in the Moberly District Medical Society, of Missouri, and his words come to us through the happy agency of the Keytesville *Democratic Print*. Dr. George M. Dewey therein portrays "The Utter Worthlessness of Sulphate of Quinine in the Treatment of Typhoid Fever," and that "bastard malady, born on the banks of the Chickahominy, whose untimely end is near at hand."

We have spoken lightly, but wish, in all sincerity, that everyone could read Dr. Dewey's paper. It is not only logical, forcible, and sensible, but it is poetical and interesting—a rare combination from a doctor's pen. Dr. Dewey advances the view, first, that quinine is given too much:

"To-day sulphate of quinine is a therapeutic despot whose autocratic sway few have the courage to dispute. At some time, in some stage of every malady, most doctors fancy they find an indication, an excuse, for giving quinine. In high fever it will pull down; in low fever it will push up.

> "No pulse so high, no pulse so low,
> But down one's neck the stuff must go."

Taking up the special subject of typhoid fever, Dr. Dewey says, "I know of no disease in which quinine can do so little good and as much harm as typhoid fever." "I hear a great deal about tissue waste from high fever. I doubt not that this is the tendency of long-continued high temperature. But the fact is, that a gallon of sweet milk will prevent more 'tissue waste' than an ounce of quinine."

The undue weight laid upon the symptom of fever since the introduction of the clinical thermometer is referred to:

"Utter neglect of temperature is far better for the patient than half-drachm doses of quinine. The quinine-druggers raise a great howl about 'tissue waste.' The fact is, tissue waste and exhaustion come from impaired digestion, and not from temperature. That quinine does this, is beyond question."

Dr. Dewey is exceedingly severe upon Dr. Hutchinson, the learned author of the article on typhoid fever in Pepper's "System of Medicine," who even in mild cases of this disease recommends the use of two or three grains of quinine four times a day.

"Now," says Dr. Dewey, "here is a man, supposed to be the Polar Star to guide American practitioners over the doubtful sea of medicine, writes down in a book (who dares dispute what he sees written in a book?) directions for giving quinine every three or four hours to a patient

with typhoid fever, whom the veriest tyro knows needs nothing but good diet.

"The patient he describes is a good one to have. A good one to get up a reputation on—one who has no diarrhœa, no delirium, no tremors, temperature of 102.°

"A clear hundred per cent. of such cases ought to recover. Why would any thinking man give such a patient quinine? He says he was *accustomed* and in the *habit* of doing this way. This is at the bottom of such nonsensical practice.

"A doctor who contributes a hundred pages to a book to guide American practitioners ought to give some better reason than *custom* and *habit* for giving medicine.

"The doctors from the land of flowers and gunpowder tea give medicine for the same scientific reason this author does—from habit, custom, tradition. Dr. I. Hun Su, of Pekin, China, treats uncomplicated typhoid fever very successfully with the following prescription:

"℞ Three inches dried umbilical cord,
One dried snake-skin,
One fresh tom-cat's head.

"Mix. Boil in five pints of water for two hours and strain. Sig.—Tablespoonful every four hours.

"This prescription would be far less apt to disorder the stomach and nervous system than quinine, besides being tonic."

Dr. Dewey next pays his respects to typho-malarial fever so called. If his words are not gospel, they are very near to it, and we shall only do justice to them and to our readers by quoting in full:

"During the late war the Yankees invented a new disease that howls and cries aloud for quinine. This bastard was baptized and christened 'Typho-Malarial Fever;' though Dr. Woodward abandoned his bantling in disgust, every malarial maniac in the land is clamorous for its life.

"Throughout the land the asses bray
The horrors of malaria.

"I believe no one claims to have any typical pathological lesions of typho-malarial fever differing from typhoid fever.

"In our last State meeting, Dr. Van Emon gave the histories of fifteen post-mortems of deaths from the so-called typho-malarial fever. In every one the characteristic lesions of typhoid fever were found. If the prefix—the tail, the malarial end—of this disease could be amputated, quinine would get its quietus from a good many doctors who only prescribe it on account of this caudal appendage.

"Some men are very contentious about characteristic symptoms of typhoid fever. Pathology ought to settle it. If a patient has a continued fever, and any one symptom known to occur in what they call a typical case of typhoid fever is absent, this is a case of 'typho-malaria.' Should a case fail to have diarrhœa, or delirium, or tremors, or petechiæ, or tympanitis, or headache, or insomnia, or stupor, bronchitis, or hemorrhage, then it would be typho-malarial fever, and absolutely require quinine.

"Hybrid diseases exist only in the brain of fools. I believe no one claims to tell the sex in bacillas.

"Which is the Sire and which the Dam,
Seems quite beyond the ken of man.

"I am told by the believers in the hybrid theory that this fever often commences as a typho-malarial fever, and runs into or ends in typhoid fever. After malaria is killed by quinine typho lives on. Some men are bent on keeping this name alive to justify the treatment.

"Our forefathers fooled a long time with biliousness to justify calomel.

"Hepatic doctors now are seen no more,
The hunt for bile has long been given o'er,
Whoever would a reputation make,
Deserts the bile, the bugs to overtake.

"Whether one believes or disbelieves in typho-malarial fever is unimportant—quinine is a deleterious drug in either."

Dr. Dewey is the St. George of the dragon quinine. We are inclined to think that in time he will succeed as thoroughly as did the legendary hero.

We have long contended against the routine use of quinine, or in fact any antipyretics in the continued fevers, and we trust that the echoes of the voice from Missouri may rumble about the world, to the perpetual benefit of febrile humanity.

A FRENCH CRITIC ON MYOPIA.

M. Francesque Sarcey, the well-known French critic, has written a little work[1] which is well worth the perusal of physicians, by virtue of its charming style, and the freshness and force with which he describes the course and the dangers of myopia.

M. Sarcey's book is an autobiography of himself just so far as it relates to his eyes. He begins: "I was born near-sighted, dreadfully near-sighted. Many physicians," he continues, "assert that persons are never born near-sighted, but only become so." We believe that ophthalmologists teach that an hereditary predisposition to myopia is very common indeed, but that congenital myopia is very rare. "However," says M. Sarcey, "Science may think what she pleases, but I was born myopic."

The very day on which his infirmity was discovered is indelibly stamped on his memory, and his account of it is quite worth transcribing:

"One day, prompted by the spirit of mischief, I got hold of the big silver spectacles which my father always wore, and clapped them on.

"Fifty years have passed since then, but the sensation I experienced is keen and thrilling to this day. I gave a cry of astonishment and joy. Up to that moment I had seen the leafy dome above me only as a thick, green cloth, through which no ray of sunlight ever fell. Now, oh, wonder and delight! I saw that in this dome were many little brilliant chinks; that it was made of myriad separate and distinct leaves through whose interstices the sunshine sifted, imparting to their greenery a thousand tones of light and shade. But what amazed me most, what so enchanted me that I cannot speak of it to this day without emotion, was that I saw suddenly between

[1] 'Mind Your Eyes.' Good Advice from a Near-sighted Man to his Fellow-sufferers. Translated (with the author's permission) from the French of Francesque Sarcey, by Henry Dickson Bruns, M.D. New Orleans: New Orleans Medical Publishing Co. 1886.

the leaves, and far, far away beyond them little glimpses of the bright, blue sky. I clapped my hands in ecstasy, I was mad with astonishment and delight."

Very high myopia like Sarcey's is rare, but moderate degrees of myopia are very common; and myopia, as Sarcey states, is increasing and spreading through Europe like some epidemic disease. Among the ancients myopia appears to have been practically unknown. As evidence of this M. Sarcey refers to the ancient amphitheatres in which thirty thousand spectators sat and viewed the games without a glass. Perhaps, to be sure, the myopes of those days might have learned to stay at home. However, that myopia is increasing there can be no doubt. In fifteen years the proportion of undoubted myopes in the Polytechnic School of France has risen from thirty to fifty per cent., and eighty per cent. of the students have to wear glasses.

M. Sarcey urges his readers with profound emphasis to remember that myopia always has a tendency to increase unless numberless precautions are taken, and that all myopic eyes are weak eyes to be looked after carefully by their possessor. In his own case the result of over-use and misuse of his eyes, especially his attempts to get along without glasses, were that he lost the sight of one eye entirely through detachment of the retina, and that a cataract developed in the other.

The loss of the eye he attributes to the effects of studying when a boy in a badly lighted school-room, and he invokes all mothers to examine the school-rooms. "If they be not fairly flooded with light take your son home again. To leave him bent for ten years over dimly lighted books, is, if he has the least tendency to this trouble, almost certainly to lay up myopia for his manhood; if he be already myopic, it is to assure him a blind old age."

Sarcey's description of the development of his cataract and of its removal is vivid and dramatic. The operation was successful, and he now sees distant objects even better than before. The epilogue to his story is: "Remember that all extreme myopia ends almost infallibly in cataract, and that nearly all myopia may become extreme if the eyes are abused."

While Sarcey's views are somewhat tinctured by the bitterness of his personal experience, his warnings are wise and timely, and should be widely read.

Some Instructive Percentages.—Dr. John H. Rauch, in his last quarterly report to the Illinois State Board of Health, says that although a reduction in the percentage of graduates over matriculates has taken place in some medical schools, it has not in all. Last year the percentages of graduates to matriculates rose as high in individual cases as 52 for regular, 57.7 for homœopathic, and 58.3 for eclectic colleges—the averages of all schools being 33.3 for regular, 32.6 for homœopathic, and 33 9 for eclectic, and the minimum 10.5, 17.6, and 15, respectively.

An American Physician Honored.—At the recent meeting of the German Congress of Internal Medicine, Dr. L. Weber, of New York, was admitted to membership in that distinguished body. It is the first time that this honor has been bestowed upon an American physician.

News of the Week.

Bequest to the New York Academy of Medicine.—It is stated that the New York Academy of Medicine has received two bequests, one of $70,000 and one of $5,000.

Canadian Medical Association.—The Nineteenth Annual Meeting of the Canadian Medical Association will be held in the city of Quebec on Wednesday and Thursday, August 18th and 19th next.

A New Instrument for Measuring the Acuteness of Hearing.—M. d'Arsonval showed to the Biological Society an apparatus for measuring auditory acuteness, or an acoumeter. This apparatus differs from other similar instruments. It is simple, and it indicates directly the proportional intensity of sound. It is composed of a sound-producer, consisting of a small tuning-fork giving the normal *la* (870 vibrations), kept at work by an electro-magnet placed according to the disposition adopted by M. Mircadier. A single-element Leclanché's battery is sufficient to keep it in function. A telephone is placed in communication with the two ends of the thread forming the coil of the electro-magnet. The telephone is thus traversed by the extra interrupted current (*extra courant de rupture*) at each vibration of the tuning fork. The tension of this extra current is much greater than that of the battery, and causes the telephone to vibrate intensely in union with the tuning-fork. In order to lessen the intensity of the sound in the telephone, it is necessary to pass a current along a glass tube full of water, by plunging a metallic stem into the water. The length of the column of water traversed by the current is increased until the intensity of the sound is reduced to its minimum, and is scarcely perceptible. The strength of the extra current, and consequently the intensity of the sound, is in inverse proportion to the length of the graduator, which lessens the sound. The length of the column of water gives the degree of the auditory sense tested.

Schmidt's Jahrbücher.—Professor Winter, who has so long and successfully edited this most valuable publication, has retired, and his place is filled by Drs. P. Möbius and Dippe, of Leipsic. Both gentlemen are well known as most able and painstaking literary and scientific workers.

An Italian Surgical Congress has just been successfully held at Rome. Among the contributions was one by Professor Ceci, recounting the history of a successful splenectomy in which the spleen was one-fifteenth of the body weight.

The Usefulness of Spaying.—The London *Hospital Gazette*, quoting our editorial upon the above subject, adds: "It is possible that on first perusing the above our readers may not wholly grasp the spirit of the writer. For their enlightenment, however, we would desire to explain that our American *confrère* very successfully combines, on suitable occasions, the offices of satirist and ethical reformer."

The Kansas State Medical Society held its annual meeting, during the past week, at Atchison.

Officers of the International Medical Congress.—*President*—N. S. Davis, of Chicago.

Vice-Presidents—W. O. Baldwin, of Montgomery, Ala.; William Brodie, of Detroit; W. W. Dawson, of Cincinnati; E. M. Moore, of Rochester, N. Y.; T. G. Richardson, of New Orleans; L. A. Sayre, of New York; J. M. Toner, of Washington; J. A. Grant, of Ottawa, Canada; the President of the American Medical Association; the Surgeon-General United States Army; Surgeon-General United States Navy; Supervising General Marine Hospital Service.

Secretary-General—J. B. Hamilton, U. S. Marine Hospital Service.

Treasurer—E. S. F. Arnold, of New York.

Chairman Finance Committee—Frederick S. Dennis, of New York.

Presidents of Sections:

Medicine—A. B. Arnold, of Baltimore.

Surgery—William T. Briggs, of Nashville.

Military and Naval Surgery—H. H. Smith, of Philadelphia.

Obstetrics—Delaskie Miller, of Chicago.

Gynecology—James H. Harrison, of University of Virginia.

Anatomy—William H. Pancoast, of Philadelphia.

Physiology—J. H. Callender, of Nashville.

Pathology—A. B. Palmer, of Ann Arbor.

Diseases of Children—J. Lewis Smith, of New York.

Ophthalmology—E. Williams, of Cincinnati.

Otology—S. J. Jones, of Chicago.

Laryngology—W. H. Daly, of Pittsburg.

Dermatology and Syphilis—A. R. Robinson, of New York.

Hygiene—Joseph Jones, of New Orleans.

Collective Investigation, etc.—A. L. Guyon.

Nervous Diseases—John P. Gray, of Utica.

Dental and Oral Surgery—J. Taft, of Cincinnati.

New York is thus represented by Drs. J. Lewis Smith and A. R. Robinson; Philadelphia, by Drs. H. H. Smith and W. H. Pancoast; and Boston by no one.

Dr. Holmes Advises Doctors to Take a Vacation.—Instead of a vacation editorial, which would naturally be looked for by our readers with eager interest at about this time, we venture to substitute a little verse from Dr. Holmes' poem, "City and Country":

> Ye healers of men, for a moment decline
> Your feats in the rhubarb and ipecac line;
> While you shut up your turnpike, your neighbors can go
> The old roundabout road to the regions below.

The New York College of Physicians and Surgeons held its annual commencement on the evening of May 13th, when a class of ninety-seven was graduated. The Alumni Association prize of $500, for an essay showing original research, was awarded to Dr. William G. Thompson, for an essay on "The Application of Instantaneous Photography to the Study of Physiology and Therapeutics." The Joseph Mather Smith prize of $100, open to all Alumni, went to the same doctor for another essay. The Harsen prizes for clinical reports were distributed as follows: First, Charles W. Wolfertz; second, A. M. Fanning, Jr.; third, divided between H. Jarecky and J. L. Corish. The address to the graduates was delivered by General Horace Porter.

Reception to the Faculty of the Post-Graduate Medical School.—Professor William A. Hammond gave a reception to the Faculty of the Post-Graduate School and a few other gentlemen of the city, at his residence on Saturday last. It was numerously attended, and was a brilliant and enjoyable affair.

The Kansas City Medical Record has had a suit for $40,000 brought against it for publishing a certain editorial. Our contemporary is confident that he will pass over no such sum to the plaintiff.

The Extract of Belladonna.—According to Mr Wyndham Dunstan, the alcoholic extracts of belladonna root range in alkaloidal strength from 1.65 to 4.45. This is due mainly to the different ways in which the extract is obtained.

The One Hundred and Twentieth Annual Meeting of the Medical Society of New Jersey will be held at the Sea-Girt House, Spring Lake, on June 8th and 9th.

Oregon State Medical Society.—The Thirteenth Annual Meeting of the Oregon State Medical Society will be held at Portland, Tuesday, Wednesday, and Thursday, June 8, 9, and 10, 1886.

The Members of the Ohio State Board of Health have been appointed. They consist of Messrs. H. J. Sharp, T. C. Hooper, D. H. Beckwith, S. P. Wise, J. D. Jones, T. C. Miller, and W. H. Cretcher. There is one homœopath on the board. There are to be two meetings held annually. Five thousand dollars have been appropriated to meet its expenses.

Ontario Medical Association.—The sixth annual meeting of the Ontario Medical Association will be held in Toronto, June 2 and 3, 1886.

Maine Medical Association.—The thirty-fourth annual meeting will be held in Portland, Me., Tuesday, Wednesday, and Thursday, June 1, 2, and 3, 1886.

A Gift to the University Medical College.—The New York University Medical College has just received a gift of $100,000 for the construction and maintenance of a laboratory building, to be known as the Loomis Laboratory. The gentleman who has made the gift wishes that for the present his name should not be made public. Land adjoining the property of the college has already been purchased, and it is hoped that the new building will be ready for occupation next year.

Actinomycosis in the Human Subject.—An example of this interesting and rare disease is reported to have been met with at the Montreal General Hospital recently. The patient, a young female adult, was thought to have died of phthisis, but the investigations of the pathologist revealed the true nature of the malady. This case is of special interest, as few, if any, authenticated cases have been as yet recorded in America. It is down for consideration at the next meeting of the Medico-Chirurgical Society.

Replacement of Lost Eyes.—The replacement of a diseased eye by the healthy eye of an animal has now been done five times, with one success. In all the cases but this one (Bradford's) the cornea sloughed. In two cases, however firm vascular adhesions took place.

Dr. D. B. St. John Roosa has been elected a Corresponding Fellow of the Academy of Medical Sciences (*Real Academia de Ciencias Medicas, Fisicas y Naturales*) in Havana, and his work upon the Ear has received a full and complimentary notice in the Journal of the Academy.

M. Pasteur and Miss Morosini.—The Paris correspondent of *The Lancet* writes: "I have had an opportunity of revisiting M. Pasteur's laboratory in the Rue d'Ulm, under the following circumstances: A young lady, a daughter of Mr. Morosini, the well-known banker of New York, who was said to have been bitten by a mad dog, was brought to Paris to undergo M. Pasteur's anti-rabic treatment. The young lady was accompanied by her parents and by Dr. Bulkley, the celebrated dermatologist of New York, who asked me to introduce him to M. Pasteur. This I gladly consented to do, and on Monday morning, the 3d inst., the day after their arrival in Paris, the young lady was inoculated with the anti-rabic fluid. But before the operation was performed M. Pasteur, as is his wont, inquired particularly into the circumstances of the case. Dr. Bulkley furnished the necessary information and produced a certificate from a well-known veterinary surgeon testifying to the dog having been really affected with rabies. The young lady was bitten on April 14th, on the space between the root of the nose and the inner angle of the right eye, which was soon after freely cauterized with the nitrate of silver by Dr. Bulkley. Nineteen days had therefore elapsed between the accident and the inoculation. During my visit at the laboratory it struck me that the hydrophobia scare had not lessened, for the place was crowded with applicants from all parts of the world. M. Pasteur is as zealous as ever, and I learn that the Emperor of Brazil has conferred on the eminent biologist the Order of the Rose."

Fixing a Standard of Medical Education.—At the last quarterly meeting of the Illinois State Board of Health, April 15th and 16th, the following resolution was passed:

"*Whereas*, The continuous graduation of forty-five (45) per cent. of the total number of matriculates of a medical college—due allowance being made for the average annual loss—must be accepted as prima facie evidence that, practically, every candidate is graduated without regard to competency or qualification; therefore be it

"*Resolved*, That no medical college be recognized as in good standing within the meaning and intent of the Act to Regulate the Practice of Medicine in the State of Illinois, the aggregate graduates of which college amount to forty-five (45) per cent. of its aggregate matriculates during the period of five (5) years ending with any session subsequent to the session of 1885-86."

A Medical College Below the Mark.—The Illinois State Board of Health has recently resolved, "That in view of the apparently irregular manner in which diplomas have been conferred by the Beach Medical Institute of Indianapolis, this Board declines for the present to receive the diplomas of that institution as the basis for certificates authorizing practice in the State of Illinois."

The Nashville Academy of Medicine and Surgery is the title of a new medical society recently organized in Nashville, Tenn.

The Eastern Medical Journal has become a monthly, and adopts regular medicine, abandoning its previous somewhat indefinite "eclecticism." It is now under the editorial charge of Dr. C. E. Nelson, of this city.

Reports of Societies.

ILLINOIS STATE MEDICAL SOCIETY.

Held at Bloomington, Ill., May 18, 19, and 20, 1886.

The Annual Meeting of the Illinois State Medical Society convened at Washingtonian Hall, Bloomington, May 18, 1886, and was called to order by the President, Dr. William A. Byrd, of Quincy.

The meeting was opened with prayer by the Rev. A. W. Bennett, D.D., of Bloomington.

After brief addresses of welcome The President delivered his annual address, in which he emphasized the advantages of medical society organizations in bringing individual members to a better understanding of their social and scientific wants, and concluded by urging the adoption of a plan for more representative membership throughout the State. The more prompt publication of the proceedings was also recommended, and in that connection the suggestion was offered that some medical journal or organ for the Society be selected for the purpose.

Dr. J. L. White, of Bloomington, read a paper on some recent cases of

CEREBRO-SPINAL MENINGITIS

as the

REPORT ON PRACTICE OF MEDICINE.

These were typical in character, and formed the foundation for some remarks regarding the general character of the disease.

In reference to treatment, the writer of the paper used quinine, but for direct effect upon the membranes of the brain and spinal cord, he believed in ergot. It had been said that opium and alcohol were always contraindicated, but he had found in his cases that the amount of these remedies tolerated by the patient was astonishing, and he believed, as a rule, that in diseases where certain remedies were tolerated in immediately large doses, these remedies were indicated, as there was no disease in which the nerves of the eye and ear were so sensitive. The usual precautions should be taken as regards the behavior of nurses, attendants, the darkening of the room, etc.

Dr. Cullom, of Jacksonville, stated that in his locality, and with the belief that the disease was of germ origin, he had recently given internally the sulph. carbolate of sodium in sixteen-grain doses, every two hours, with apparent benefit.

Dr. Whitinger, of Matamora, had been through an epidemic of the disease, and his experience was very similar to that of the author of the paper. He thought he had good results by evacuating the bowels, steaming with the hot pack, and giving ergot and bromide of potassium.

Dr. Barnes, of Bloomington, had been through an epidemic and lost nearly every case, until he finally did nothing but give bromide of potassium, and his cases got well.

Drs. Walter Hay, of Chicago, Worrell, of Bloomington, C. M. Noble, Goodell, and others took part in the discussion.

Dr. Truesdale, of Rock Island, read

THE REPORT ON SURGERY.

He thought that as an antiseptic carbolic acid stood at the head of the list; further, it was an excellent local anæsthetic, and it was the most efficient capillary hæmostatic in the surgical world. Its most important place, however, was in

MYOFIBROMATA OF THE UTERUS.

He had treated a case of this kind, injecting about a drachm of a six per cent. solution by an aspirating needle right through the abdominal wall into the tumor, and repeated the same operation every few days. The patient improved in every respect, the tumor gradually decreasing in size. Several other similar cases were reported as being treated in a like manner and gradually improved in every respect. All the cases had done well, causing no bad after-effects. He next spoke of

THE TREATMENT OF CARBUNCLE

by the same remedy. He believed this malady to be a purely local disease in the true skin. In treating this affection he injects a hypodermatic syringeful of a six-per-cent. solution of carbolic acid into the centre of the tumor. The advantage of this strength of solution over one of nearly full strength is that it will never produce a slough, which the strong solution will certainly sometimes do.

Dr. Goodell had had several cases, and they were treated by nearly all remedies except the one suggested, and they had all died. Hereafter he would try the carbolic acid.

THE REPORT ON OBSTETRICS

was made by Dr. Ellen A. Ingersoll, of Canton, and consisted of several complicated labor cases.

Dr. Park, of Bloomington, commenced a paper by an interrogation as to

HOW LONG A FŒTUS COULD LIVE AFTER A RUPTURE OF THE MEMBRANES AND EXPULSION OF THE LIQUOR AMNII, AND COULD THE MEMBRANES BE REUNITED BY NATURE AFTER RUPTURE?

He then cited cases wherein there had been a discharge of liquor amnii or other fluid for some time previous to confinement. It was necessary, first, in answering the above interrogations to know whether there was rupture of all the membranes or only of the amnion, leaving the chorion intact. Next, it might be possible that the rupture was in the upper part of the membranes and only allowed of an overflow, as it were. He thought there must have been complete rupture and discharge in some of his cases, and therefore concluded as his belief that a child could live and flourish with complete rupture of membranes and discharge of the liquor amnii three months before delivery.

A paper was read by Dr. Catherine Miller, of Lincoln, who referred to

MENTHA PIPERITA AS A LOCAL ANÆSTHETIC.

She did not, however, wish to put it on a par with the popular local anæsthetic, cocaine. She uses it largely in burns, and reported cases in point. She had used it also in chilblains with equal success.

Dr. Tilley had used the remedy with great benefit in one-per-cent. proportion with vaseline in coryza.

THE REPORT ON DERMATOLOGY

was then read by Dr. Henry J. Reynolds, of Chicago.

In his remarks on

ACNE

he spoke of the procedure recently proposed by Dr. Shewell, of Brooklyn, for that disease, viz., the passing of sounds in the male urethra, and cited the cases more recently reported by Dr. Denslow, of St. Paul, of the beneficial result of this supplementary measure in the treatment of acne. For the deep or indurated form of this disease he always lances those papular indurations deeply, and invariably found pus at the bottom, with a tendency to burrow still deeper, rather than to come to the surface. He then, to prevent the wound from healing over on the surface, which it is otherwise sure to do, and leave the miniature subcutaneous abscess to go on as before and remain indefinitely, passes a probe dipped in carbolic acid to the bottom, and fills the whole incision from bottom to top with a small piece of absorbent cotton, and leaves it to granulate from the bottom, which it will never fail to do, leaving only an almost invisible scar. He referred to a suggestion made by Dr. Fox, of New York, as to the possible, if not probable, cure of leprosy if the proper moral effect could be brought to bear on these patients, stating that the moral effect was usually depressing in the extreme, banished as they usually are from society, and imprisoned for life, as it were, with only the promise of a most miserable existence and a lingering death. He alluded to the pigmentary syphilide, and to a case reported by Dr. R. W. Taylor, of New York, and one by himself, of this condition. He next referred to the treatment suggested by Dr. Bulkley for carbuncle without incising and poulticing, viz., ointment containing ergot and oxide of zinc locally, and sulphide of calcium and a saline laxative with iron internally. He also spoke of the treatment so highly recommended by Dr. Hibberd, of Richmond, Ind., of applying, with friction, every three hours, oleate of morphia. He then, in speaking of urticaria, said that Jassar claimed to have reduced the frequency and cut short the duration of violent attacks of this disease by giving twenty-four-grain doses of salicylate of sodium, repeated every two hours, until three doses had been taken.

Brief reference was then made to the use of

COCAINE IN DERMATOLOGICAL PRACTICE.

He had found it to be of some service to allay itching in certain cases of eczema and in pruritus, and in strong solution. He had used it to relieve the pain incidental to the removal of superfluous hair by electrolysis, but the remedy was not sufficiently absorbed by the skin, as a rule, to be very beneficial.

Dr. Tilley had used the actual cautery, with a very small wire passed down to the bottom of the acne pustule, which seemed to work admirably. He had always found pus in the bottom of these indurated lesions.

THE REPORT ON PHYSIOLOGY

was made by Dr. Wetmore, of Waterloo, on "Herditament."

It was discussed at some length by Dr. J. J. M. Augear, of Chicago.

Dr. Tilley, of Chicago, in his

REPORT ON OPHTHALMOLOGY AND OTOLOGY,

summarized the observations of Dr. H. Schick, in his study of the interchange of fluids in the eye of the rabbit, by the use of the hypodermatic injection of uranine solution, with special reference to the regeneration in the aqueous humor. In reviewing the work of Dr. Stgermann, of Petersburg, it appeared that without exception

THE HUMAN EYE AT BIRTH IS HIGHLY HYPERMETROPIC.

The average of the degree of hypermetropia during the first month gives a hypermetropia of 5, 37 D., and during the second month of life H. 3, 30 D. One practical point came out in the report, viz., that infants are very indifferent to the influence of atropia when applied to the conjunctiva. The report embraced an extensive reference to the works of D. W. Einthoven on the peculiar phenomenon of a simultaneous observation of two colors red and blue—on a dark background, on actual cautery in its application to the eye; precautions in cocaine, and the result of section of the chorda tympani in scraping out granulations in the ear.

(To be continued.)

THE AMERICAN CLIMATOLOGICAL ASSOCIATION.

Third Annual Session, held at the Hall of the College of Physicians, Philadelphia, Pa., May 10 and 11, 1886.

The meeting was called to order at 3 o'clock, P.M., by the President, WILLIAM PEPPER, M.D., LL.D., of Philadelphia.

The President opened the session with an address on "The Causes and Distribution of Consumption in Pennsylvania."

DR. A. L. LOOMIS, of New York, read a paper on

THE EFFECT OF HIGH ALTITUDE ON CARDIAC DISEASE.

in which he gave his experience in twenty-six cases, several of which were described.

In the summer of 1880, while at St. Regis Lake, in the Adirondacks, the author was requested to see a gentleman who had just arrived, and was thought to be dying. The patient, forty years of age, was found gasping for breath, cyanosed, with no apparent radial pulse, and bathed with profuse perspiration. Neither heart-sound could be heard. Under the hypodermatic use of digitalis, morphia, and brandy he improved. The following day it was learned that he had left New York apparently perfectly well. When he reached an elevation of one thousand feet the breathing became difficult, and as a higher altitude was reached the difficulty was increased, and was accompanied by cardiac palpitation and a sense of oppression in the epigastrium. When he reached St. Regis Lake, at an elevation of two thousand feet, he appeared to be dying. Physical examination showed well-marked dilatation of both ventricles, with a loud systolic murmur heard over the præcordia and transmitted a little to the left. At the end of three days he returned to New York. As he reached lower levels the difficulty of breathing diminished, and when he reached the level he could walk on it. The irregular heart action, however, continued, and the feet soon became œdematous, and he died six weeks later with general anasarca and heart insufficiency. No autopsy was made. The patient had never presented any evidence of cardiac disease prior to his trip to the mountains.

Mrs. S——, forty-three years of age, had mitral insufficiency for over ten years, but never exhibited any cardiac symptoms. She went to Colorado. When she reached an elevation of four thousand feet she was suddenly seized with extreme dyspnœa and pulmonary hemorrhage. There was palpitation of the heart and constriction of the chest. The following day she started on her return. As she reached a lower level she improved. Physical examination revealed extreme dilatation of both ventricles, complete cardiac diastolism, indistinct apex-beat, crepitation over the base of both lungs, with feeble or absent respiratory murmur. The patient died four weeks after her return. The autopsy showed both ventricles much dilated, old thickening and insufficiency of the mitral valve, some interstitial myocarditis and degeneration of the muscular fibre of the heart-walls. The right lung was the seat of pneumonia and old infarctions. All the other viscera were in a state of extreme venous congestion.

B——, aged forty-six, with aortic insufficiency, and moderate eccentric hypertrophy, visited the Catskill Mountains. After a walk was seized with great difficulty of breathing, cyanosis, and unconsciousness. The next day he was somewhat relieved. He returned to his home three days later; œdema of the feet supervened, albumen and casts were found in the urine, and the patient died three weeks later. At the autopsy both ventricles were dilated, the walls of the left side were hypertrophied, the aortic valves were thickened and contracted, the heart-walls were the seat of chronic interstitial myocarditis; the kidneys were cirrhotic and the lungs congested and œdematous.

The last case reported was that of Mrs. T——, aged fifty. She had always been well, with the exception of an attack of rheumatism ten years previously. Eighteen months before she had had an attack of cardiac palpitation, which was relieved by the use of digitalis; she went to St. Regis Lake, and soon complained of epigastric oppression, palpitation, dyspnœa, and great prostration. Both ventricles were found dilated with a soft systolic murmur at the base. There was no marked cyanosis or œdema, the urine was scanty, but contained neither sugar nor albumen. Under digitalis and stimulants she improved, but in a few days the symptoms returned, vomiting came on, the pulse became more rapid and feeble, attacks of syncope occurred, and she died three weeks after the onset of the unfavorable symptoms. No autopsy could be obtained.

Dr. Loomis then went on to say that in all the cases coming under his observation the ventricular dilatation was unquestionably the cause of the sudden development of distressing symptoms, and that the commencement of the fatal issue seemed to be directly due to the effects on the cardiac circulation of a change from a lower to a higher altitude.

The two important factors which lead to permanent cardiac insufficiency are, first, the condition of pulmonary distention consequent upon rarefaction of the atmosphere, and, second, the resultant condition of the circulating blood. In the first the terminations of the vagus are excited by the distention of the lungs; by the excitation of these afferent fibres, the cardiac walls and inhibitory ganglia of the medulla are paralyzed or weakened. The inhibitory control being lost, the diastolic intervals shorten and the rhythm is increased, but the amount of work accomplished is not proportionate to the visible cardiac energy. The change in the blood which acts as an important and ultimately the principal factor in producing the cardiac insufficiency is the deficiency in oxygen. The vaso-motor centre, influenced by the want of oxygen in the blood-supply, excites a general contraction of the arterioles of the body, filling the veins and affording a large heart-supply while the arterial pressure rapidly rises as the peripheral resistance is increased. Ordinarily the heart would relieve itself by excitation of the cardio- and vaso-inhibitory centres, but these centres are held in abeyance by the condition of the blood circulating in the medulla. This increase in the intracardial pressure cannot continue, and sooner or later the heart passes into a state of diastolic relaxation which is the primary step of a condition of ventricular dilatation. It is not improbable that the blood, heavily laden with carbon dioxide, also acts as a disturbing factor of the normal action of the heart through this same afferent mechanism.

If the explanation of the effects of high altitude upon the cardiac circulation be accepted, the risks which one with even slight cardiac insufficiency runs by passing from a lower to a higher altitude is certainly very great, and if the insufficiency is extensive, such changes become immediately dangerous. It must be remembered that cardiac insufficiency may exist in those who give no evidence of it.

DR. FRANK DONALDSON, of Baltimore, read a paper entitled,

A PRELIMINARY ACCOUNT IN REGARD TO CERTAIN CIRCULATORY AND RESPIRATORY CHANGES OBSERVED IN ANIMALS PLACED IN THE PNEUMATIC CABINET.

The experiments had been performed by Professor H. N. Martin, of the Johns Hopkins University, and the writer. The animals employed were rabbits which had been chloralized. It was found:

1. When the animal is breathing air from outside of the cabinet, rarefaction of air within the cabinet causes a marked fall of general arterial pressure, but has no

influence on the pulse-rate. The fall of pressure lasts only a short time (ten or twenty seconds), and is often followed by a temporary rise above the normal.

2. This fall of systemic arterial pressure depends on two factors: greater flow of blood to the skin when the air around the animal is rarefied, and greater accumulation of blood in the lungs when they are distended.

3. Of these two factors, accumulation of blood in the lungs is the more effective, for if the animal breathes air from the cabinet, and not from the outside, rarefaction of the air within the cabinet, in this case accompanied by no special expansion of the thorax, has but a trivial effect in lowering arterial pressure.

4. When the animal is breathing external air, rarefaction of the air within the cabinet usually has no effect upon the respiratory rate nor upon the extent of individual respiratory acts, unless the fall of blood-pressure be considerable. If it be considerable, symptoms of anæmia of the medulla oblongata show themselves. In some cases there is more forcible dyspnœic breathing, and in some dyspnœic convulsions similar to those which occur when an animal is bled to death and due to the same cause, viz., deficient blood flowing through the respiratory centre.

5. The rapid recovery of general arterial pressure while the animal is still in a rarefied atmosphere, but breathing external air, is probably due to excitation of the vasomotor centre, which, as is well known, is excited whenever the blood-supply is defective.

6. The brain enclosed in a rigid box, which is practically unaffected by variations in the atmospheric pressure, has its circulation more disturbed in the pneumatic cabinet than any other organ with the exception of the lungs.

7. Compression of the air within the cabinet while the lungs are in communication with the external air, causes a considerable transient rise of blood-pressure. This is probably mainly due to the forcing of the blood from the cutaneous vessels, but there has not yet been sufficient time to thoroughly investigate this point.

8. Compression of air within the cabinet while the lungs are in communication with the external air, slows the pulse as the arterial pressure rises. This is probably due to excitation of the cardio-inhibitory centre by increased intracranial blood-pressure. Further experiments are, however, necessary before this can be positively stated.

9. In certain cases, when the air within the cabinet is rarefied and the animal is breathing external air, the respiratory movements cease altogether for several seconds. As to the cause of this physiological apnœa, we are not yet ready to form an opinion. It may be due to extra accumulation of air in the alveoli of the lung, or to distention of the lungs exciting those fibres of the pneumogastric which tend to check inspiration.

EVENING SESSION.

DR. H. F. WILLIAMS, of New York, read a paper—

A CLINICAL REPORT OF CASES TREATED BY PNEUMATIC DIFFERENTIATION.

With the assistance of Mr. Ketchum, the inventor of the apparatus, a demonstration of the working of the pneumatic cabinet was given.

The speaker then reported forty-five cases in addition to those previously reported in which he had used the cabinet as a method of treatment. Sixteen cases were reported in detail.

DR. VINCENT Y. BOWDITCH, of Boston, read a paper entitled

TEN MONTHS' EXPERIENCE WITH PNEUMATIC DIFFERENTIATION.

The speaker endeavored to give the clinical results of the treatment in twenty-seven cases since June 30, 1885. Pulmonary phthisis, in its tubercular and non-tubercular forms; bronchitis, in its acute and chronic forms, with and without emphysema or asthma, and retraction of the lung from long-standing pleuritic effusions were the diseases which he had treated in the pneumatic cabinet. His experience was such that although he had been unable to accomplish thus far such brilliant results as some others had claimed, yet he felt convinced of the very marked beneficial effect of the cabinet in many cases where other means had failed to give relief, and of its curative power in one case of incipient tubercular trouble, and he looked forward with hope to what may be done in the future with this new method of treatment.

DR. I. H. PLATT, of Brooklyn, N. Y., read a paper on

THE PHYSICS AND PHYSIOLOGICAL ACTION OF PNEUMATIC DIFFERENTIATION.

The effect of reduced air-pressure upon the periphery of the body is to increase the expansion of the thorax in inspiration and to diminish its contraction in expiration, consequently to increase the amount of residual air. By the increased pressure in the lung it will tend to exsanguinate them, and to raise the arterial blood-pressure in the general circulation.

Two of the claims put forward by Dr. Williams and Mr. Ketchum he believed to be unfounded. The first is that the effect of removing a slight degree of pressure from the periphery of the body is radically different from that of increasing the pressure of the air entering the lungs; the former acting as a vis a fronte, the latter as a vis a tergo. One of the most elementary principles of physics teaches that suction is not a force operating from in front, but is merely the removing the pressure from one side of a body and allowing the undiminished pressure to act upon the other side. It makes no difference whether pressure is taken from the outside of the thorax, or added to the inside; in either case it is the unbalanced pressure which causes the increased expansion. The other proposition which he combated was that the spray or vapor used in conjunction with the differential process can be carried further into the air-passages, or more thoroughly condensed upon them, than a spray or vapor could be under normal conditions. They cannot be carried so far, for the reason that the residual air is increased, and consequently the inspired air, which carries the vapor or spray, cannot penetrate so far. It is claimed that the vapor of medicinal substances is condensed in the lungs during the differential process by the compression consequent upon the commencement of the expiratory act. This is impossible, first, because compression only acts to condense a saturated vapor, and the air-passages cannot be saturated with the vapor of a medicinal substance, and secondly, because no greater compression is produced at the commencement of the expiration under the influence of differential pressure than under other circumstances. Such compression as does occur is due to the resistance offered by friction of the bronchial tubes and by the narrow opening of the glottis, and it is impossible that these should be affected by the differential pressure.

I believe that such benefit as results from the use of the cabinet is due mainly to the reduction of congestion in the lungs by the air-pressure within them and by the increased expansion and movement of the lungs favoring their greater action and modifying their nutrition.

TUESDAY, MAY 11TH—SECOND DAY—MORNING SESSION.

The First Vice-President, DR. FRANK DONALDSON, of Baltimore, in the absence of the President, occupied the Chair.

The report of the Committee on Health Resorts was received and ordered published in the "Transactions."

The first paper was by Dr. Roland G. Curtin, of Philadelphia, Pa., on

ROCKY MOUNTAIN FEVER.

The speaker, in the first place, referred to a communication received from Dr. D. G. Dougan, of Denver, Col., bearing upon this subject. The experience of Dr. Dougan had led him to regard all cases of mountain fever as belonging to one or another of the well-known already classified varieties. The cases, however, present variations from the usual course of the fevers to which we would assign them. Some of the cases are ephemeral in character and difficult of classification. The fever especially designated by the name mountain fever presents many features of typhoid fever. The following were some of the reasons for believing these cases to be an irregular or mild type of typhoid fever. Such cases are usually seen at the season of the year when typhoid fever is most prevalent; they occur most commonly under conditions favorable to the development of typhoid fever; not infrequently cases will present some characteristic feature of typhoid, leaving no doubt as to the diagnosis; in the high altitudes where mountain fever is said to occur a large proportion of the cases of undoubted typhoid pursue a remarkably mild course.

In 1868, Dr Curtin had seen in Wyoming Territory four cases which had been diagnosed as mountain fever. At some point in the disease all these cases had diarrhœa, and in one it was continuous. One of the patients died suddenly at the end of three weeks, but no autopsy was made. In one case there was a doubtful eruption. One of the cases had epistaxis in the beginning of the illness. Tympanites was more or less marked in all cases. Dr. Curtin considered these cases to be typhoid or typho-malarial in character. Sometimes the cases belonged, in all probability, to the class termed simple continued fever. The diagnosis of mountain fever was doubtless in large part the result of incompetency on the part of the observers, and the use of the term is continued largely as a result of fashion.

HOW THE THERAPEUTIC VALUE OF OUR MINERAL WATERS MAY BE INCREASED.

was the title of a paper by Dr. C. C. Rice, of New York.

The following conclusions were advanced:

1. Physicians should make a careful analysis of our mineral springs.

2. The medicinal values of the waters should be tested by clinical investigation, and the conclusions published for the benefit of the profession.

3. If the waters are found to present marked merit, the physician should interest himself in developing the springs, improving the bath houses, etc.

4. Physicians in sending patients to the springs should be more careful to select the proper water and should send with the patient the diagnosis and history of the condition, for the benefit of the physician at the baths.

5. The patient, while at the bath, should be under a more rigid medical discipline.

6. The social life of our watering-places should be reorganized.

The following papers describing the climates of various places were then read: "The Climate of Mexico," by Dr. Didama, of Syracuse; "The Southern Adirondacks," by Edward T. Bruen, M.D., of Philadelphia; "The Climate of El Paso, Tex.," by Dr. E. W. Schauffler, of Kansas City; "Southern Pine Park," a new health resort in North Carolina, by Dr. A. N. Bell.

Afternoon Session.

The following officers were elected:

President—Dr. Frank Donaldson, Baltimore.

First Vice-President—Dr. V. Y. Bowditch, Boston.

Second Vice-President—Dr. Roland G. Curtin, Philadelphia.

Secretary and Treasurer—Dr. J. B. Walker, Philadelphia.

Additional Member of Council—Dr. F. C. Shattuck, Boston.

Elected to Membership—Dr. F. Donaldson, Jr., Baltimore; Dr. G. R. Butler, Brooklyn; Dr. W. Matthews, U.S.A., and Dr. J. H. Musser, Philadelphia.

The following memorial was presented by Dr. J. Ewing Mears, secretary of a special committee of the American Surgical Association appointed to consider the proposition with reference to the establishment of a Congress of American Physicians and Surgeons.

Washington, D. C., April 30, 1886.

To the President of the American Climatological Association:

In view of the fact that there are a number of special medical organizations now in existence in the United States, each having for its aim and attainment the advancement of the special department of medicine for which it was organized; and since the members of said special societies are of the representative men of the profession in America, many of whom are, at the same time, fellows or members of several of these special societies, which double membership, if it may be so expressed, necessitates them, if desirous of attending two or more of the meetings of these societies the same year, to make as many separate trips from home, and often with much loss of time to themselves and inconvenience to their patients. Therefore, it appears necessary that some arrangement should be made with the different societies as to a uniform time and place of holding their sessions, so that those members who wish to attend the meetings of more than one association may be enabled to do so without useless expenditure of money or unnecessary loss of time.

An extended correspondence, together with personal conferences with many of the most prominent of the fellows of this and other of the associations, has disclosed the fact that there is a decided and growing inclination to unite the various societies into a common whole, whereby it would become a general organization, representative of the various special departments of the profession in America.

The plan proposed, and which is offered for consideration, is to unite the following named associations into a Congress based upon the outlines which are now to be explained: American Surgical Association, American Ophthalmological Association, American Otological Association, American Neurological Association, American Laryngological Association, American Gynecological Association, American Dermatological Association, American Climatological Association, and American Clinical and Pathological Association. These associations to be united under the name and style of "The Congress of American Physicians and Surgeons."

The plan of organization hereby submitted, and subject to any alterations or amendments which may be deemed wise and proper, is that each society will preserve its own name, constitution, and by-laws, elect its own officers and fellows, hold its own sessions apart from the others at the time and place of meeting, publish its own transactions, and do all other acts of which, by virtue of its constitution and by-laws, it has the inherent right to do, thus preserving its own autonomy.

The Congress to be composed of these special societies when in convention, and its meetings to be held annually in the city of Washington, the most appropriate place for the assembling of such an organization. The constitution and by-laws of the Congress to be formed by a committee composed of a like number chosen from each separate society. The opening session of each annual meeting of the Congress to be devoted to such general business as may pertain to the interests of the association as a whole. The Congress to be presided over by a president, elected annually, and who shall deliver the opening address upon the first day of the session.

The manner of choosing the president to be as follows: By a nominating committee composed of one member elected from each special association, or otherwise, as may be determined upon by the special society itself, this committee nominating one or more candidates for the office of president, whose election is to be by ballot on the last day of the annual session, and in a convention of all the societies assembled. The presidents of the special societies to become, *ex-officio*, vice-presidents of the Congress. Membership in the Congress to be acquired only by virtue of fellowship in one or another of the special associations. Other officers of the Congress to be elected or appointed, as may hereafter be determined upon by the associations in convention.

These are the outlines of a union proposed for the consideration of the members of this Association, which, if it should meet their approval, can be submitted to the action of the societies which have been mentioned. It was suggested that the Chair appoint a committee of five to bring the subject before the next special association which meets this spring or coming summer, and which, in the event of a concurrence of opinion on the part of said society, shall act in concord with their committee appointed to confer with the other societies in the order of their meetings. This enlarged committee to report at a convention of all the societies, which shall be requested to hold their next annual meetings at the same dates in the month of June, 1888, in the city of Washington.

To avoid any confusion as to the time of next meeting, each society (this year) could adjourn to meet in June, 1888, leaving the date to be fixed by the enlarged committee after their work of conference had been finished, it then being only necessary to apprise the secretaries of the respective associations, who will give notice to the various fellows or members.

This proposition is the result of calm consideration, and has been approvingly indorsed by quite a number of the representative gentlemen of the profession, both in and out of this special association.

The plan proposed is simply to unite into one great body the already existing special societies, and it is proposed from the honest conviction that such a union will prove of inestimable benefit to them individually and collectively.

The special committee appointed by the American Surgical Association to consider the above memorial, reported that it viewed with great satisfaction the perfection of a plan through which the meeting of the associations above named in the city of Washington, at the same time of the year, may be accomplished, and the meeting of all the associations in general assemply on such days as may be determined, for the purpose of delivering addresses upon general subjects in medicine, such meetings to be held without any formal organization through which the associations meeting will sacrifice their autonomy.

To accomplish these purposes, the committee offers the following resolution:

Resolved, That a committee of five fellows of this association be appointed, which shall be authorized to confer with committees of other associations interested in the adoption of a plan of a convention as hereinbefore stated, and report upon the same at the next meeting for the action of the association.

The resolution was adopted, and the following committee was appointed in accordance therewith: C. H. Mastin, M.D., Mobile, Chairman; C. T. Parkes, M.D., Chicago; J. Ford Thompson, M.D., Washington; N. Senn, M.D., Milwaukee; J. Ewing Mears, M.D., Philadelphia, Secretary.

The proposition was approved, the committee to be announced later.

Dr. Henry B. Baker, of Lansing, Mich., read a paper

ON THE CAUSATION OF PNEUMONIA,

with a number of illustrative diagrams showing the relation of deaths from pneumonia to various meteorological conditions. The temperature curve was based on 154,400 observations. There were recorded 5,473 deaths from pneumonia in Michigan. Certain conditions are so uniformly associated with sickness from pneumonia is the night ozone; but it probably not the controlling factor. The amount of ozone is largely controlled by the temperature. Variations in atmospheric pressure, relative humidity, as well as absolute humidity, also seem to have a causal relation to pneumonia; but these conditions are under the influence of temperature. The investigations show that pneumonia is directly, or indirectly, caused by a comparatively low temperature. The work goes to prove, in a scientific manner, the truth of more or less widespread beliefs since the time of Hippocrates.

The mucous membrane of the bronchial tubes exposes a surface of fourteen hundred square feet. A large amount of water is taken out of the body by the lungs is very great. In Michigan the amount of vapor exhaled in excess of that inhaled is greater in January than in July. One reason is that less vapor enters the lungs with the air at a low temperature. As the air is warmed in the lungs its capacity for moisture is increased, and its demand for water is great. The fluid that passes into the air-cells contains the salts of the blood, some of which—as the chloride of sodium—do not readily pass off. An unusual accumulation of chloride of sodium occurs in the lungs. This probably favors the exudation into the lungs of albuminous constituents of the blood. Whether the ultimate fibrinous character of the exudate in the lungs is due to the blood-plaques or is a result of the oxidation of the albumen otherwise induced before or after exudation, it may be well to notice that the diagrams present a close relation between the curves of atmospheric ozone and pneumonia.

Dr. J. H. Musser, of Philadelphia, read a paper entitled

SUGGESTIONS REGARDING THE PREVENTION OF PHTHISIS IN MILL HANDS.

The speaker stated that it was rather to prevent that state of the system which often leads to phthisis that he desired to make some suggestions. The suggestions more particularly referred to factory laborers. He showed that states of ill-health were common in this class of artisans, and asserted that it was very largely due to an inadequate supply of food, which was improperly selected and prepared, and to carelessness in attention to digestion. This cause obtained more largely than bad hygienic surroundings, or than the occupation itself.

If this be true the remedy proposed was to have the plan of the Willimantic Cotton Company used by all mill proprietors. That company has proved, by experience and careful calculation, that it pays them in quality and quantity of work done to supply milk to their boys and bouillon to their women twice daily, and that the health of the operatives is promoted and their lives prolonged thereby. Dr. Musser trusted that the members of the Society could influence proprietors to adopt this plan and therefore close one of the avenues to disease and death.

Dr. C. L. Dana, of New York, read a paper entitled

A STATISTICAL INQUIRY REGARDING THE RELATION OF HIGH ALTITUDES TO NERVOUS DISEASES.

The speaker presented the results of inquiries made, at his request, of twelve physicians living in Colorado Springs, regarding the effects of high climates on the nervous system in health and disease. The majority thought that chorea in children was more frequent there than in lower altitudes; that the climate was bad for nervous women. The high altitudes do not necessarily injure epileptics, and in anæmic cases might cause improvement. Insomnia dependent upon anæmia and malnutrition was benefited and generally cured. The climate has no specific influence for good upon diseases of the spinal cord, and, if anything, the contrary. The speaker

was of the opinion that high altitudes had a tendency to excite lithæmia and arthritism, with consequent irritating effects upon the nerve-centres. The best effects of the climate were seen in anæmic insomnia, neurasthenia, and melancholia.

Dr. G. R. Butler, of Brooklyn, read a paper on "Mitral Stenosis," giving the histories of fourteen cases.

The President announced as the committee to confer with the committees of other special societies, with reference to the establishment of a "Congress of American Physicians and Surgeons": Dr. A. L. Loomis, New York; Dr. F. Donaldson, Baltimore; Dr. F. C. Shattuck, Boston; Dr. E. T. Bruen, Philadelphia; and Dr. W. W. Johnson, Washington.

It was resolved to appoint a committee of three, with Dr. C. C. Rice as chairman, to investigate the therapeutical properties of the different mineral springs.

After passing a vote of thanks to the College of Physicians for the use of their hall, the Society adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

SOCIETY MEETINGS—THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION—EXCISION OF THE KNEE-JOINT FOR UNUNITED PATELLAR FRACTURE—HISTOLOGICAL CHANGES IN HYDROPHOBIA—MEDICINE AND ART—CHANGES OF PROFESSION.

London, May 7, 1886.

With the approach of summer—and, at last, of genuine summer weather also—the medical societies are all making preparations for "shutting up," and by next month the last of the society meetings will have been held. The British Medical Association forms a notable exception, for its branch meetings continue to be held, and the great annual meeting will, as always, be held at the end of July. As Brighton is to be the place of meeting this year, a very large attendance may be expected, for Brighton is only an hour and a half by rail from London, and is so easy of access to, and so frequented by, Londoners that it is often called "London-on-Sea." The fact that Dr. Billings is to give an address will prove an undoubted attraction. Though not so well known by name as Dr. Flint, I am sure he will draw a good audience. I well remember the enthusiasm with which his address on "Medical Literature," at the International Medical Congress in London (1881), was received. At its conclusion the President of the Congress (Sir James Paget) rose, and after referring to the native wit and wisdom contained in Dr. Billings' address, said that it alone, without any other contribution, would have sufficed to render the Congress memorable. The applause with which Sir James Paget's remarks were received showed his audience to be in full agreement with them. I recall the scene vividly. Dr. Flint's name is widely known and esteemed on this side of the Atlantic, and his loss will no doubt be felt at the Brighton meeting, but I have no doubt that Dr. Billings will well fill the gap, and do much to make the meeting a success.

At the last meeting of the Clinical Society a brief discussion took place on the treatment of fractured patella. Mr. Lunn exhibited a patient who had twice sustained this injury to his left patella. The first fracture united. The second, which occurred six months after the first, would not do so. There was wide separation of the fragments, and the patient was miserable from the pain he suffered, and from the knee constantly giving way under him. After he had been in this condition sixteen years Mr. Lunn excised the knee-joint, and wired the femur and tibia together with silver wire. The operation was performed antiseptically, and six weeks afterward the limb was put up in plaster-of-Paris, and the patient allowed to get about on crutches. A useful limb was the result. The patient was forty-four years of age at the time of the operation, which age, remarked Mr. Lunn, was considered rather an advanced one at which to perform excision of the knee-joint. Mr. Timothy Holmes expressed approval of the treatment pursued by Mr. Lunn. Modern notions had been much modified as to age, he said, and he had himself excised the knee-joint in patients over forty, and had seen successful cases in older people. Professor Humphry, he believed, had performed the operation with success in one patient over sixty. Mr. Holmes said he considered wiring the patella a rash proceeding in recent cases of fracture, and some old cases did not yield good results after wiring, but would do well with excision. Mr. Gould remarked that wiring the patella gave the patient a movable knee instead of a stiff joint, as after excision, though he admitted that Mr. Lunn's patient possessed a useful limb, and that in some cases excision might be essential.

At the last meeting of the Pathological Society, Dr. Hale White showed a series of specimens taken from two men and a dog who had died of hydrophobia. From the histological study of these specimens, Dr. White concluded that the essential lesion was an acute inflammation in the floor of the fourth ventricle spreading upward to the brain and downward to the cord. There was some blurring of the secretory epithelium in the salivary glands, and a few leucocytes were seen among the gland elements. In one case the thyroid was atrophied. The pneumogastric and sympathetic nerves were examined, as was also every organ in the body, but no changes were found.

No medical artist has an exhibit at this year's Royal Academy exhibition, though there is a notable collection of medical portraits, busts, and statues by professional artists. Sir Henry Thompson has no work in the "Academy," though he exhibits a beautiful Italian landscape at the Grosvenor Gallery. Yet many of our profession possess no mean skill with the brush, pencil, or burin. As etchers, Mr. Seymour Haden and Dr. Evershed have attained considerable repute. The former is a surgeon (now retired), who some few years ago created some stir by his denunciation of the current insanitary methods of burial in solid wooden or leaden coffins. Numerous vigorous letters from his pen appeared in the *Times*, giving graphic descriptions of some graveyard explorations, and advocating the employment of perishable coffins. Dr. Evershed is a practising physician and is attached to one of the consumption hospitals. Many other names might be mentioned. Of art connoisseurs our profession has had, and still has, many within its ranks. Among these the late Dr. Billing was noteworthy for the valuable collection of gems and cameos he possessed. Turning to the sister art, the drama, more than one medical man has appeared on the stage. One distinguished ophthalmic surgeon in London, now enjoying a large and lucrative practice, had formerly, I believe, some idea of devoting himself entirely to the dramatic art.

The above are all instances of doctors who, while remaining in their own profession, yet have shown special skill or interest in another. Yet entire changes of profession have often occurred. The transition from medicine to science is most easy, and a large proportion of our eminent scientists have been brought up as medical men, and some have practised as such. As instances may be mentioned Professor Huxley, Sir Joseph Hooker, Dr. Bayley Balfour, Dr. Odling, Professor Crum Brown, Professor Martin Duncan, and Professor Sanderson. Literature furnishes many similar examples. The present editor of one of the most popular of our monthly magazines is a medical man. Divinity, too, has proved to many of our profession a more attractive study than medicine, and not a few doctors have ceased to be practitioners in order to become ministers of religion. Law has not attracted so many votaries; still, it has

lured some from clinical pursuits. At least one medical man has lived to be a judge, and an eminent queen's counsel now living was not only brought up to the medical profession, but actually practised it for twenty years, attaining some repute as an obstetrician. It is interesting to note that he has educated his son for his adopted, not for his original, profession. I have known an instance of a converse change. A young man who had been brought up as a solicitor tired of law and forsook it for medicine. I have also heard a lawyer express the wish that he had been a doctor. Many doctors in this country are tempted—on financial grounds—to wish the opposite. Law offers rewards such as medicine cannot, and is the pathway to honors denied to the sister profession.

OUR PARIS LETTER.

THE LABORS OF PASTEUR.

[PARIS, April 30, 1886.

THE universal interest now taken in the Pasteur treatment of hydrophobia induces me to lay before your readers a short account of the method adopted by that eminent biologist for the prevention of that appalling malady. The history of M. Pasteur's remarkable discovery is so well known that a repetition of his preliminary experiments on animals would be superfluous. I may, however, briefly relate that his first experiments in connection with hydrophobia were made in December, 1880. It will be remembered that he collected, by means of a camel's-hair brush, some mucus from the mouth of a child aged nine years which had died from hydrophobia in a hospital in Paris. The child had been bitten in the face by a dog in a village near Paris. It was ascertained beyond doubt that the dog was mad. The mucus was removed from the child four hours after death. Two rabbits were inoculated with it, and these animals died thirty-six hours afterward. Other rabbits were then inoculated from them, some with the saliva, others with the blood. The second series of rabbits died more rapidly after inoculation than the first, the third series more rapidly than the second, and so on through several successive series of animals. He then performed experiments with the view of ascertaining the period of incubation of rabies in animals of the same species; for instance, if a rabbit be, after trephining, inoculated under the dura mater with a fragment of the spinal cord removed from a mad dog, hydrophobia always appears after an incubation period which, on an average, covers fifteen days. This period of incubation is shortened by the transmission of rabies from one rabbit to another, so that after a series of twenty-five rabbits it is reduced to eight days, and after another series of twenty-five rabbits to seven days. The reduction of the period of incubation could not be further diminished by the transmission of the malady to another series of forty animals. M. Pasteur admits that the virulence of the contagium then attains its highest degree. In dogs, in which the period of incubation is fifteen or sixteen days when they are inoculated with the rabic virus recently taken from a stray dog, it would be reduced to ten or eight days when they are inoculated with virus prepared in the manner already described.

The following is a brief description of the mode of procedure adopted by M. Pasteur for inoculating animals: The rabbits, which are the animals most frequently employed, are chloroformed. A longitudinal incision of two centimetres is made through the integuments in the frontal region, then a portion of bone of six millimetres in diameter is removed with a trephine, and under the dura mater thus exposed is injected a drop of the infecting fluid by means of a Pravaz's syringe, the extremity of the nozzle of which is bent at right angles. The wound is washed several times with carbolic acid during the operation; it is united by sutures, and the animal is then removed to its box. Rabbits generally bear the operation well, and, with a few rare exceptions in which small abscesses are formed, no real complication has been observed. The clinical aspect presented by the inoculated animals corresponds with that termed dumb rabies ("rage muette"); in dogs the paralytic form of rabies is for the most part observed. The preparation of the attenuated virus is effected in the following manner: The animal which has died of rabies is fastened to a plank with the back upward. An incision is made through the skin along the spine, extending from the skull to the coccyx, and the dorsal muscles are detached. The spinal canal is opened from behind with a red-hot iron; the spinal marrow and the meninges are removed with a knife and pincers equally heated to redness, and then these organs are placed on a flat plate previously sterilized, in which they are divided, with scissors disinfected, into pieces of six centimetres, which are immediately fastened with a thread to the stopper of a bottle prepared for the purpose, in which it is suspended. These bottles are of the volume of two litres, at the bottom of which is laid some caustic potash about two centimetres deep to maintain the air in the bottles in a dry state. Besides the usual opening at the top of the bottles there is another lateral opening near the bottom, both of which are stopped with sterilized wadding. The bottles are then arranged in a well-ventilated room, the temperature of which is kept constantly at 20° Centigrade. The pieces of marrow commence to get dry in about three or four hours, and are completely so in four or five days.

The virulence of these pieces of marrow is nil after fourteen days; at the end of nine, eight, or seven days, one can produce rabies in rabbits by inoculation. At the sixth day the virulence gradually diminishes. The diminution of the virulence depends on the temperature, the lower the latter is the less the virulence diminishes. For inoculation, pieces of dried marrow a few millimetres long are emulsified in a quantity of fowl-broth sterilized four to six times greater. The inoculations are commenced with the weakest virus (that of fourteen days), and the subsequent inoculations are continued step by step to the stronger. The inoculations are finished with the strongest virus, which infects the rabbit from the sixth to the seventh day, and a dog from the eighth to the ninth day. In this manner M. Pasteur was able, in a long series of experiments, without a single negative result, to render animals insusceptible ("réfractaire") to rabies. As regards the length of the duration of the immunity, he is not yet in a position to decide. He has under his care fifty dogs that he considers insusceptible to hydrophobia, and now and then he infects some of them with recent rabic virus. In another species of experiments M. Pasteur occupied himself with the question as to whether the immunity is transmitted from one generation to another. The first experiments performed by him on guinea-pigs appeared to give positive results. If this should be confirmed, the importance of such a result in practice can hardly be overrated.

These experiments were begun in November, 1882, of which he made a report to the Academy of Sciences on October 26, 1885. A period of three years had therefore elapsed between that time and when this communication was made, without the slightest interruption in their course. No other virus had been used than that removed from rabbits which had died from hydrophobia after successive inoculations, so that M. Pasteur had always at his command perfectly pure virus, always, or very nearly, identical. This he considers to be the essential condition of his method. The cords of the rabbits inoculated are virulent throughout their entire length, and equally so. Encouraged by the results obtained by him in animals, M. Pasteur was induced to apply his method to the human subject, and, in his report to the Academy of Sciences above referred to, he stated that on July 6, 1885, he inoculated his first subject, Joseph Meister, an Alsacian youth, at his laboratory in the Rue d'Ulm. The boy had been bitten in fourteen different

places, on the hands, legs, and thighs. But before inoculating the boy, M. Pasteur consulted MM. Vulpian and Grancher, who considered the patient to be almost sure to die from hydrophobia. This first experiment, however, caused M. Pasteur great anxiety, as the dogs rendered refractory to hydrophobia by his method had not been bitten by a mad dog before attaining that condition; but he knew by previous experiments, that dogs which had already been bitten were easily made refractory to hydrophobia. The lad Meister was inoculated thirteen times in ten days, though, at present, M. Pasteur only makes ten inoculations, one every day. Each successive inoculation is made with a more virulent fluid than the preceding one. The last inoculations of Meister were made with a rabid virus taken from a mad dog, and rendered more virulent by being passed by inoculation from rabbit to rabbit. This virus produced hydrophobia in rabbits after seven days' incubation; and in a dog not inoculated for rabies after an incubation period of eight or ten days. As Joseph Meister is in perfect health, and it is nine months ago since he was bitten, and then inoculated, M. Pasteur concludes that he has escaped what appeared to be an imminent danger.

In my next I shall continue this report on M. Pasteur's inoculations.

STATE REGULATION OF THE PRACTICE OF MEDICINE IN NORTH CAROLINA.

To the Editor of The Medical Record.

SIR: In your issue of February 6, 1886, is an editorial on the above subject, in which you comment upon the wisdom, expediency, and justness of the Medical Act as passed by various States and Territories, the highest mead of praise being awarded to the State of North Carolina, as being the most crucial in its requirements of legal qualifications for the practice of the healing art. You, in the same issue, give, with a repressed smile of pitying ridicule, some of the erroneous answers of the young medical men applying for State grants to prosecute the profession of medical practice.

We have long and patiently waited for some able champion to arise in the cause of the much-abused, oppressed, and sneered-at young medical man, but none seem anxious to join the losing side. We, therefore, ask that you give us space for our exposition of the Medical Act as it now exists in this State.

The Medical Act of the General Assembly of North Carolina of 1884 and 1885 makes it a misdemeanor for anyone to practise medicine or surgery in the said State, except such an one as had a previously procured certificate from the State Medical Board, or a diploma from some reputable medical college, issued prior to January, 1880.

Now we claim that the above law, in its exclusive favors to a certain class, is highly unjust, not only robbing the younger members of the profession of advantages which they have purchased for themselves through days of arduous toil, but at the same time placing them in the very falsest light before the laity. The young medical men of North Carolina are as much in favor of stringent laws and examinations, in order to keep out incompetents, as the wildest and grayest enthusiast in the State; but they do object to the implication made in the law that their education alone is defective; that they alone require the eliminating influences of the act, while those who had the good fortune to graduate prior to 1880 are folded in the fostering arms of the law, shielded from every untoward circumstance, and permitted to practise medicine and surgery without let or hindrance from any source. "Yea, ye are the people, and wisdom will die with you."

Are the facilities for acquiring a medical education less now than in ante-bellum days, when two professors could exhaust, in the allotted time, the limited curriculum, and our gray-haired sages received from their Alma Maters the permit to go forth and heal? I trow not. Is it a fact that the mental endowments of those young men who have graduated since 1880 are of a lower grade than of those who graduated prior to that time? No one can so affirm. Then why this distinction without a difference? Why are we, graduates of the best schools in the country in the year 1880, forced to leave our practice in the hands of jealous and watchful rivals, to incur the expense of travel, the mortification of an examination, and probably the chagrin of defeat, while our more fortunate confrere, a graduate of 1879, enjoys all the immunities of the law and all the privileges of the profession without debarment from anyone? Why not pass an act either to *include all*, or else make the law refer only to the incoming members of the profession?

The answer to the query is easy. The instigators of the law worked wisely in their own interest. They accurately measured their ground and knew how far to go. They well knew that the graduates of the last five years were, as a rule, without money, position, or influence, and any law against their interest and privilege would meet but slight opposition. They knew, further, that a bill to include all the physicians practising in the State would not only include themselves, but would be so unpopular as never to become a law, the legislators not daring to vote for such a measure. They therefore drafted such a bill as would be sure to pass, and, at the same time, give them an advantage over that minority element in the profession—the selfish hate of whom is equalled only by the fear of their ultimate success.

In observant experience we willingly yield the ground to age, but as a class we are ready, under any and all circumstances, to measure with the older members in all that pertains to the technique of our common profession. We object to no law that is equal and fair for all men. We object to no examination, however stringent, which everyone wishing to practise in the State is required impartially to pass; but we do object, and shall forever object, to distinctions being made against us for no other than spiteful and arbitrary reasons.

When will those members going before cease to retard the progress of those coming up behind? Why, say they, we are erecting for you a higher standard of excellence, in order that you may become better informed and more skilful medical men. Thanks, you remind us of the innocent Wall Street babes pleading before their country's tribunal for the poor working-men. The examples you set we are willing to follow; but we do not aspire to the egotistic position of leaders.

It is highly probable that the younger members are not the only ones in the medical profession to whom it would be a benefit, both to themselves and the communities in which they live, to have their memories refreshed by an examination upon matters medical. The answers given by the applicants mentioned in your article of February 6th, are not more ridiculously *outre* than many errors of old and well-experienced men which have fallen under my own observation. I have heard a noted physician speak of the great sciatic nerve as being on the top of the thigh. I know a physician of many years of active practice examine a patient with the bi-aural stethoscope, placing one aural tube at the base of the scapula, and the other on the nipple, and applying his ear to the trumpet extremity, gravely assure the patient that his lungs were normal, since he could hear nothing with his instrument of precision to impeach their integrity. Another noted physician of this State—one officiously instrumental in having the offensive bill passed—was unable to state *even the number* of bones in the cranial vault or in the face, when requested to do so, as an expert witness in a famous murder trial, by the counsel for the State. Yet all these are wise and well prepared for their work, while the unfortunate who was so unlucky as to pass his degree subsequent to 1880 is subjected to annoyance, expense, and often chagrin, by this unjust and unequal legislation.

The crime of being young and inexperienced we will

not attempt to palliate or deny; but we do hope that our faults and inefficiencies may cease with our youth, and that we be not of that number who continue to be ignorant, selfish, and vindictive, in spite of experience and the mollifying influences of time. As young men we ask no favors. Treat us as the rest are treated, and for what remains we will take care of ourselves. Were the law universally inclusive, then would we with you join hands in its praise. NORTH CAROLINIAN.

THE CASE OF DR. FANCOURT BARNES.

TO THE EDITOR OF THE MEDICAL RECORD.

IN THE MEDICAL RECORD of April 24, 1886, in the column devoted to "News of the Week," it is stated, on the authority of the *Journal of the American Medical Association*, that the charge that Dr. Barnes stole my dictionary is an unjust one, because Dr. Barnes' book contains several thousand words more than mine. You also say you would be glad to see Dr. Barnes' name cleared.

I assert that this charge against Dr. Barnes is true. A careful comparison of the two books, made by myself and others, has shown that, with one or two exceptions, he has reprinted all my words and definitions, even to the errors, misprints, punctuation, etc. There is such careful copying of all these throughout a sequence of several thousand words as to show that the resemblance could not have been so consecutively exact had not Dr. Barnes' printer used my printed page as part of his copy. His book contains very few strictly *medical* terms not found in mine. The mass of his padding consists of chemical, botanical, and pharmaceutical terms to be found in all the general dictionaries. A prominent journal, in reviewing Barnes' book, said that his additions were "not particularly, or at all, scientific." In many cases, after giving certain of my words and definitions, he has repeated the same word, giving another combination of definitions, evidently taken from the common dictionaries. Here and there a word was accidentally misplaced, with regard to its alphabetical position, in my dictionary; it receives the same malposition in Barnes' book. I have in my possession overwhelming proof of all that I claim. I wrote to this effect to all the prominent British journals, but, with one exception, they refused to publish my communication.

My dictionary is an original work, exactly as claimed in its preface, and was the product of years of hard study. Had it been reprinted in England as "Cutter's Dictionary," I should not have even protested; to steal such a work in the manner this has been done, is to inflict a much greater injury than to reprint an essay or work of that nature. Respectfully,

G. R. CUTTER.

55 PELHAM AVENUE, BROOKLYN.

THE CAUSE OF DIABETIC COMA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Having noticed your editorial in THE MEDICAL RECORD of April 17, 1886, "The Cause and Prevention of Diabetic Coma," I wish to call your attention to a theory advanced by Stadelmann on the same subject.

In the course of former investigations Stadelmann found that in those specimens of urine of patients with diabetes mellitus in which a large amount of ammonia was contained an abnormal (pathological) acid—in most cases oxybutyric acid—was regularly likewise present. In regard to excretion of ammonia it was observed that the quantity of the same was very variable. Exclusive meat diet exerts a constant effect on the quantity of ammonia in the urine. Meat diet is to be considered as acid-producing nutriment, and as such it withdraws ammonia from the system, and consequently the urine of diabetics, when they live on exclusive meat diet, contains larger quantities of ammonia than when they live on mixed diet. Stadelmann further proved that the reaction of the urine on chloride of iron told nothing as to the presence of the pathological acid contained therein. Moreover, he found the excretion of ammonia in general to be at the same time in proportion with the excretion of the pathological acid. The diabetic often excretes seven to nine times more ammonia than when in a normal condition. According to Stadelmann, the diabetic coma is to be regarded as an acid intoxication of the blood, which poisoning is caused when the human system is no longer capable of producing the amount of ammonia necessary for the neutralization of the acids they pathologically formed. Under such circumstances the fixed alkalies of the blood, to a large extent, are withdrawn from the same by neutralization; they then are not able any more to combine with the carbonic acid formed in the tissues, and a dangerous overcharge of the tissues with carbonic acid is the result. The picture of acid intoxication, as produced by Walter, by means of feeding rabbits with muriatic acid, shows, likewise, as essential symptoms, dyspnœa, accelerated breathing, and weakness of heart. Stadelmann, supposing that diabetic coma was caused by acid intoxication, had already, at some former occasion, recommended the administration of carbonate of sodium in case of coma; but he advises to give it *not* per os or per clysma, but by means of direct intravenous injection, thus to bring it directly into the blood. He found in experimenting on animals that as much as 140 to 160 grammes of carbonate of sodium can safely be injected. Further, Stadelmann recommends, as a preventive measure against the danger of diabetic coma, the abundant administration of alkalies, especially when exclusive meat diet is commenced. The sudden change to exclusive meat diet (acid nutrition) favors the appearance of diabetic coma. A. ROSE, M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 9 to May 15, 1886.

HUNTINGTON, DAVID L., Major and Surgeon. Ordered to proceed from this city to David's Island, New York Harbor, on public business connected with the reconstruction of the present hospital building at that depot, or the erection of a new one. On completion of this duty to rejoin his station. S. O. 109, A. G. O., May 10, 1886.

FINLEY, JAMES A., Captain and Assistant Surgeon. Ordered for duty at Fort Buford, D. T. S. O. 39, Department of Dakota, May 5, 1886.

BENHAM, R. B., Captain and Assistant Surgeon. Ordered to Department of the Platte. S. O. 109, A. G. O., May 10, 1886.

CHERBONNIER, A. V., Captain and Medical Storekeeper, U.S.A. Granted leave of absence for four months, with permission to apply for four months' extension. S. O. 109, A. G. O., May 10, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 15, 1886.

BRANSFORD, J. F., Surgeon. Invalided, home from Pacific Station.

WINSLOW, GEO. F., Surgeon. Ordered, June 1st, to the U. S. S. Atlanta.

HEFFINGER, A. C., Passed Assistant Surgeon. Detached from the Navy Yard, Portsmouth, N. H., and ordered to U. S. S. Atlanta, June 1st.

ENUCLEATION WITH TRANSPLANTATION AND REIMPLANTATION OF EYES.

By CHARLES H. MAY, M.D.,

INSTRUCTOR IN OPHTHALMOLOGY AND ASSISTANT IN [illegible] CLINIC [illegible] TO MEDICAL [illegible]

THIS operation being one of very recent date the literature of the subject is quite limited, and is embodied in Section I., History of the Operation. The remainder of these pages have been divided into Section II., Summary of Results Obtained, with a Study of the Changes taking place in the Transplanted Organ; Section III., Record of Cases; and Section IV., Peculiarities and Management of the Rabbit when kept for Experimental Purposes—this last section comprises the results of the writer's experience in this direction, and may prove useful to future experimenters.

I. HISTORY OF THE OPERATION.—The first mention of this operation is recorded in the *Revue Générale d'Ophthalmologie*, May 31, 1885. The following is a translated abstract: The operation was performed by Dr. Chibret, on May 4, 1885. The staphylomatous and buphthalmic eye of a girl of seventeen was removed, and the eye of a rabbit inserted into the conjunctival sac; sutures were passed from the patient's conjunctiva into the margin of the cornea above and below, and the transplanted organ thus kept in place. The eye was then bandaged. The operation was a failure, for on the fifteenth day the cornea, which had gradually been changing from hazy to an ulcerated condition, sloughed away, and the eyeball was destroyed. This failure the originator of this operation attributed to contact of threads with the cornea and the thinness of the rabbit's cornea. He claims to have had a rather sudden and complete return of sensibility of the transplanted cornea on the tenth day; the vascular and muscular union of the transplanted eyeball the operator found good.

Subsequently, in the same journal, under date of October 1, 1885, Dr. Chibret reviews the operation, and condemns further transplantations until reports shall have been furnished giving the results of the operation in animals.

Transplantation was next performed by M. Terrier, June 15, 1885; his report to the Société de Chirurgie of Paris, December 2, 1885, reviews the operation, and gives the results of this and a subsequent transplantation. In this (the second recorded case), sloughing of the cornea resulted on the third day.

The third case was one of M. Rohmer, June 22, 1885, and the cornea was destroyed on the seventh day.

The next transplantation was performed by Dr. H. W. Bradford, of Boston, and is reported in *The Boston Medical and Surgical Journal* of September 17, 1885. His method differed from previous ones in that the optic nerve was sutured to the stump of nerve remaining upon the globe of the rabbit's eye, considerable subconjunctival tissue was left, to which the muscles of the orbit were united, and the conjunctival sac sutured to the margin of conjunctiva left surrounding the rabbit's cornea. The observation ends on the eighteenth day after operation, and the following is the reported result: "Conformation and tension good; cornea improving (it had been hazy—C. H. M.), and has cleared peripherally so as to allow the iris to be distinctly seen; chemosis of the conjunctiva has disappeared, although the membrane remains congested; exposed sclerotic on outer side of eye practically covered by the conjunctiva; ocular movements in all directions good." This case is reported as a successful one.

The fifth and final reported case was performed by M. Terrier, October 19, 1885, and, although he adopted part of Dr. Bradford's plan, the operation was a failure.

Thus, of the five operations, four were failures—the cornea sloughing in each case. Even the successful Boston case is rendered doubtful by the fact that the report extends only over eighteen days, and in the following pages cases of operations by the writer are reported, where the cornea remained of good consistence, though hazy, for fifteen or sixteen days, and yet sloughed afterward when exposed to the atmosphere. A letter to Dr. Bradford asking for further developments in his case was not answered.

In four of these cases the rabbit's eye was employed; in one, a dog's eye—this was, however, one of the unsuccessful cases. Leaving out Dr. Bradford's case, the others are admitted failures; so that, at best, the success of the operation has not been established. By operating upon a large number of rabbits, the writer has been enabled to observe and record the following results.

II.—SUMMARY OF THE RESULTS OBTAINED, WITH A STUDY OF THE CHANGES TAKING PLACE IN THE TRANSPLANTED AND REIMPLANTED ORGAN.—The results of the series of twenty-four operations presented by the writer certainly justify repeated trials upon the eyes of man—at least the transplantation of the rabbit's globe into the human conjunctival sac, and succeeding in this, the transplantation of one human eye into the orbit of another. There are, however, moral objections to the disabling of one human being for the cosmetic improvement of another.

The operation must be placed among the perfectly feasible ones. Take Cases 24, 23, 21, 16, and 15, comprising one reimplantation and four transplantations. In these the bandage having been kept well in place throughout for twenty-one, twenty-one, twenty-eight, thirty-four, and thirty-six days respectively, the condition of the transplanted organ at the end of these periods was very favorable; the eyeball was of good conformity, the cornea hazy but clearing, and the tension good. Any one of these eyes, just as they are at time of writing, would be a great improvement upon many staphylomatous or atrophied eyeballs, or those the seat of dense white leucoma. Then, again, the artificial eye is a foreign body, and from time to time excites inflammation; it has to be renewed every two years, and is an item of expense, especially if an artistic match to the other eye is desired. In rabbits all colors of irides may be obtained (the writer has not yet met with a pale blue one), brown, black, gray, dark-blue—here would be a sufficient assortment of colors to choose from in order to match the human eye.

In size the rabbit's eye is smaller than the adult human globe; it varies from 18 to 23½ mm. in diameter. Were there any demand for rabbit's eyes, large sized animals could be bred for this purpose. [The writer is now attempting this, having for the doe an animal whose eyeball measures 23½ mm. transversely, and a buck of equal size for the purpose.]

The arrangement of muscles in the rabbit is identical with that of the human eye. The ophthalmoscopic appearances of the fundus of the rabbit are somewhat different from those in man—the arrangement of blood-vessels is the same.

One result of the series of operations it is very important to remember: *In no case was there any rise of temperature or any apparent interference with the general health, or the slightest implication of the sound eye.* Hence, even though the operation fails, no injury will have been done, for even in all the unfavorable cases a stump remained at least as good as that resulting after ordinary enucleation, while in most of these cases the stump afforded a better rest for an artificial eye than would have been obtained in an ordinary enucleation.

Method of operating.—The operations were done with strict antiseptic precautions. The instruments were washed and wiped with alcohol, and previous to use dipped into a saturated solution of boric acid. The eye was kept wet constantly with a solution of corrosive sublimate (1 to 10,000). Two rabbits of equal size being chosen, they were anæsthetized, and a spring speculum introduced beneath the lids of the eye to be removed to keep the lids apart. With forceps, the conjunctiva and Tenon's capsule over the insertion of the rectus superior were raised, cut into with the blunt straight scissors; with the blunt hook the muscle was caught, a thread passed through muscle and conjunctiva to secure both, and the insertion of the muscle divided. This was done with each of the recti muscles, and the intervening conjunctiva was cut at about an eighth of an inch from the corneal margin. A thread was then passed through the conjunctiva of the eyeball opposite the superior rectus, and knotted so as to give the relations of the eyeball after removal. The subconjunctival tissue around the eyeball having been severed and as much as possible having been left upon the eyeball, the latter was made to protrude and the optic nerve divided by blunt-pointed scissors curved on the flat, at about an eighth of an inch from its entrance. The enucleated eyeball was now placed in a saturated solution of boric acid and covered by cotton.

The eye of another rabbit was enucleated in a similar manner. After hemorrhage had ceased in the socket of the first rabbit, the optic nerve was sought for, caught with the forceps, and the smallest-size catgut suture, previously soaked in the sublimate solution and threaded upon a very delicate curved needle, passed through it at about an eighth of an inch from the extremity; the same needle was then passed through the stump of the nerve attached to the eyeball of the second rabbit, the two ends approximated by tightening the suture, the latter tied twice and cut off short. By means of the four threads attached to the recti muscles and conjunctiva, the conjunctival sac was drawn over the eyeball and then stitched to the margin of conjunctiva left surrounding the cornea of the transplanted organ; this was done by eight stitches of smallest-size iron-dyed silk; four of these stitches were passed through recti muscles and overlying conjunctiva on the one hand, and secured to the rim of pericorneal conjunctiva on the other; the remaining four passing in the intermuscular intervals and securing the two edges of conjunctiva only.

The eyeball having been thoroughly washed with solution of bichloride (1 to 10,000), the lids were sewed together by two silk sutures transfixing their edges, white vaseline smeared over them, and successive disks of borated cotton applied so as to form a firm and even compress. Over this a $\frac{5}{8}$ inch (four yards long) flannel bandage was applied, the turns alternating, some horizontal above supraorbital rims, some vertical passing between ears, over affected eye, and beneath the jaw; the unoperated eye was left uncovered. The whole was covered by a specially contrived chamois mask; the latter consisted of two lateral pieces of chamois, laced below the jaw, and in the median line of the upper surface of the skull, and provided with openings for the ears, for the unbandaged eye, the neck, and mouth, so that every part of the skull was enveloped with the exception of the parts mentioned; this chamois covering was tightened by lacing, and was sewed on the underlying bandage at several places so as to prevent slipping. The bandages were left on, when possible, a week, or longer, before removal; and such thorough antisepsis did the bichloride solution insure that suppuration under the bandage was the exception. The operations lasted about one hour; the transplanted eyes remained in the boric-acid solution from ten to twenty minutes (this time being necessary for enucleating the second eye, checking hemorrhage, and securing the nerve). The animal recovered rapidly from the effects of the ether.

Considerable difficulty often presented itself in catching up the divided optic nerve and in passing the suture. Hence the writer suggests the following special forceps and needle: The forceps consists of an ordinary fixation-forceps, the extremity of which is concave internally, and when closed presents a circle the circumference of which corresponds to that of the optic nerve, and provided with fine teeth; an eighth of an inch above the termination is an opening to admit the passage of the threaded needle. The latter is a very delicately rounded needle, curved almost at right angles, the point flattened from side to side, provided with a fine opening, and mounted upon a holder. The special forceps grasps the end of the nerve and holds it while the needle and catgut transfix it by passing through the opening near the extremity of the forceps.

Changes in the transplanted and reimplanted eyeballs.—The first seven cases were left unbandaged, and degeneration (sclerosis or sloughing) of the cornea was the invariable result. The next seven cases were bandaged, but the method was unequal to the task of preventing displacement or removal from the incessant attempts of the animal to get off the dressings; the result was that the cornea degenerated (sclerosis or sloughing) soon after the bandage was removed, though it had remained in good condition while the dressings were well in place. In the remaining ten cases, the bandage was displaced in Cases 17 and 18 and was removed, put on too tightly and had to be removed in Cases 19 and 20; here, again, the cases progressed favorably until the bandage became displaced and had to be removed. It might be asked why the bandages were not made to stay on sucessfully; a consideration of the shape of the skull in the rabbit will explain this—were the bandage applied too tightly, it would interfere with the movements of the jaw and also produce excoriations of the skin, if too loosely, the animal succeeded in getting it off; so that this obstacle to the success of the operation in eighteen out of the twenty-four cases was a considerable one; in six cases it was overcome by the aid of the chamois covering.

Throughout the experiments all unbandaged operated eyes were washed out thoroughly with the bichloride solution (1 to 10,000) twice a day, and this was also done when the dressings were removed prior to rebandaging.

In six cases (15, 16, 21, 22, 23, and 24) the bandage stayed in place throughout, and the result was very favorable and satisfactory.

This proves that protection of the cornea from atmospheric contact is essential; when this was maintained, success was the result. The influence of the atmosphere is easily explained—the *cornea remained insensitive throughout in all cases*, the ciliary nerve-supply having been cut off; foreign bodies in the atmosphere settling upon the cornea excite no sensation, and remaining, without being washed off by the tears and movements of the lids, produce inflammation and degeneration of the cornea. This was well illustrated in the cases in which no bandage was applied; in all of these cases, the portion of the cornea which was first to slough—in fact, the only portion which sloughed at all—was a central elliptical portion corresponding to the part most exposed.

Synopsis of the History and Results of Case

No [illegible]

By watching closely, the writer found that in sleeping the animals did not close the lids completely on the affected side, and the central elliptical portion corresponded to the space left between their margins. In other cases, in which the bandage had become displaced, the sloughy portion of the cornea corresponded to the exposed portion; in one case, in which the stitches holding the lids together had been rather loosely applied, a linear area of degeneration of the cornea showed where it had been exposed. Thus, the effect of atmospheric traumatism upon the insensitive cornea is clearly and indisputably established. The cornea must be protected until there is a return of sensibility. The parts supplied by direct branches from the fifth nerve, such as the nares, lids, and nasal mucous membrane, were not affected in any of the cases.

Under the microscope, the degenerated corneæ were found to be infiltrated with small, round, and polygonal, and larger fusiform cells, chiefly between the corneal fibres, and the latter were more opaque than normal; the epithelium of the surface was wanting in some places, and at others was markedly increased in numbers, causing a heaping up of cells.

The rapidity with which the ocular muscles attached themselves to the transplanted eyeball was wonderful; it occurred as early as the third day—in most cases by the seventh day, in a few only as late as the tenth day. This muscular connection was ascertained by dissection, and by associated movements transmitted from the other eye—a piece of carrot or some bright object was passed in varying directions in front of the sound eye, and the transplanted organ watched for associated motion; it was also ascertained (when the animal paid no attention to these objects) by moving the eyeball in varying directions with forceps, and noting the amount of resistance. Under the microscope the muscles showed very little fatty degeneration.

The connective-tissue union between the eyeball and surrounding capsule of conjunctiva was also effected quite rapidly; in one case (22) being considerable at the end of four and a half days, as found by dissection.

Vascularity of the rim of conjunctiva attached to the transplanted eyeball was demonstrated in one case of reimplantation on the fifth day, and in most cases on the eighth or tenth day; it would show itself by a red rim around some portion of the cornea, and between the eighth and tenth days, in most cases, blood-vessels could be traced with the naked eye, passing from the palpebral to the ocular conjunctiva and thence to the rim of conjunctiva of the transplanted organ.

The tension of the eyeball began to diminish as early as the sixth hour (allowing a slight diminution present in all cases after enucleation), in most cases on the second day, when no bandage was applied; when bandaged well, tension remained normal throughout.

In some of the unbandaged cases the conformity of the eyeball was retained, and the eyeball simply the seat of atrophy and hardening; but in most of these unprotected eyes the cornea sloughed, the contents of the eyeball escaped, and a small or medium-sized, non-sensitive, retractive stump remained. In the bandaged cases the conformity of the eyeball remained good.

The changes in the optic nerve presented the well-known Wallerian degeneration; even with lower power enlargement, the difference, as shown by Weigert's copper-hæmatoxylon staining, was well marked in all cases;

the central end of the nerve was found to terminate abruptly and to be the seat of degeneration. In all cases there was union of the sutured ends of the nerve, even in one case (22) examined four and one-half days after suturing; the intervening substance between the central part of the nerve and the eyeball consisted in early stages of granulation tissue (small round-cells with very little intercellular elements), in later stages of fusiform cells mingled with connective-tissue fibres, some fat-vesicles and blood-vessels; later still, the connective tissue became firmer, but no nervous elements passed between eyeball and nerve in any case examined; the retinæ were invariably degenerated. The point of junction, where the nerve had been sutured, presented usually a small bulbous enlargement so as to have a greater diameter than the nerve itself; the catgut suture had been absorbed in all cases.

III. Record of Cases.—*Case* 1.—Large black doe. Operated January 30th. Removed L. E. and inserted L. E. of Case 2. Eye somewhat bulging after operation, but lids can close. No bandage applied.

Six hours: Cornea slightly hazy. T. n.

Second day: Cornea very dull and hazy. Considerable pus adheres to eyeball and lids. T. —.

Third day: Cornea very hazy and sloughy. T. —.

Fourth day: Ulceration of cornea corresponding to an elliptical area in centre.

Sixth day: Ulceration deeper. T. — 2.

Seventh day: There is slight associated muscular action.

Eighth day: Some of contents of eyeball have escaped through perforation in ulcerated part of cornea; a scab now covers the perforation. There is a slight vascular zone around the margin of the cornea.

Eleventh day: The eyeball has gradually shrivelled. Globe is small and hard. Perforation in cornea has closed. Cornea densely opaque.

Post-mortem appearances: Globe of left eye much smaller than right, and is white and anæmic, excepting around margin of cornea. L. E. measures 16 x 15 mm.; R. E. measures 18 x 18 mm. Right optic nerve at junction with eyeball is 1½ mm. in diameter, that of left eye measures 3 mm. transversely at same point. Conformation of R. E. normal. Left eye small, cornea completely opaque and hard, globe shrivelled. There is good connective-tissue union between ocular conjunctiva and eyeball; muscles are firmly attached to eyeball rather farther back than in normal eye; blood-vessels can be seen to pass from palpebral conjunctiva to that surrounding the cornea; palpebral conjunctiva appears normal. At situation of suture of nerve catgut cannot be demonstrated; there is a mass of tissue forming an oval enlargement and uniting the globe to the nerve. Brain apparently normal.

The unoperated eye has remained normal throughout. Cornea of transplanted eye has been insensitive throughout. At no time has there been any elevation of temperature or other apparent interference with general health.

Case 2.—Medium-sized black buck, operated January 30th. Removed L. E. and inserted L. E. of Case 1. No bandage applied.

Six hours: Cornea very slightly hazy, and epithelium denuded from an elliptical area over centre.

Second day: Cornea more hazy. T. n. Very little inflammatory reaction in lids.

Third day: Cornea hazy. Parts beyond cannot be seen. T. —.

Sixth day: Cornea is now quite opaque, but shows no tendency to slough; the elliptical central portion is of a denser white color than rest of cornea. There is associated muscular action.

Ninth day: All stitches have come out. Eyeball moves extensively and cornea is in centre of palpebral fissure.

Twelfth day: Blood-vessels are seen to pass from palpebral conjunctiva to margin of cornea.

Fourteenth day: Eyeball has diminished in size and is now quite small.

Fifteenth day: Cornea, which until now was smooth, though densely opaque, now looks sloughy.

Sixteenth day: Cornea begins to slough, chiefly in central elliptical portion.

Seventeenth day: Cornea has sloughed away and contents of eyeball have escaped; lens was soft and white, vitreous like boiled starch.

Eighteenth day: Scab covers opening in cornea.

Twentieth day: Nothing but a small, retracted, reddened stump now remains.

Forty-first day: Condition the same. Cornea has remained insensitive throughout. No implication of sound eye at any time. There has been no elevation of temperature, nor apparent interference with the general health at any time.

Case 3.—Small white and gray doe. Operated February 2d. Removed R. E. and inserted R. E. of Case 4. Eye bulges very little after operation. No bandage applied.

Six hours: Cornea slightly hazy. T. n.

Second day: Cornea more hazy, especially in central elliptical portion. T. n.

Third day: Cornea almost milk-white in color. T. n.

Fourth day: Slight epithelial abrasion over central elliptical portion.

Fifth day: There is slight associated muscular action.

Sixth day: Central elliptical portion has become denser and whiter than the rest. Epithelium still denuded over this area. T. n.

Eighth day: Pericorneal conjunctival vascularity visible.

Twelfth day: T. — (slightly). Whole cornea densely opaque, but central elliptical portion still more so. Eyeball anæmic, but remains of good size.

Thirteenth day: T. — 1. Cornea has assumed a yellowish color. Lids are somewhat swollen, and considerable pus exudes, causing their agglutination.

Fifteenth day: Cornea looks sloughy, especially at central elliptical portion. T. — 2.

Sixteenth day: Contents of eyeball have escaped through perforation in sloughing cornea. Nothing now remains but a small suppurating stump.

Twentieth day: Small, retracted stump remains; this no longer suppurates and eyelids have closed over it.

Fifty-first day: Small, non-irritated stump remains. Cornea has remained insensitive. Other eye has remained normal. There has been no elevation of temperature, no apparent interference with general health at any time.

Case 4.—Small gray and white buck. Operated February 2d. Removed R. E. and inserted R. E. of Case 3. No bandage applied.

Up to twelfth day progress identical with that of Case 3; after this more favorable than 3.

Thirteenth day: T. n. Cornea densely opaque, especially at central elliptical portion. Blood-vessels can be seen to pass from palpebral conjunctiva to that surrounding margin of cornea.

Sixteenth day: T. — (slightly). Form of eyeball preserved, but eye is smaller than the other.

Thirtieth day: Condition the same. Post-mortem examination shows eyeball atrophied, cornea densely opaque, form of eyeball preserved, muscles firmly attached, conjunctival sac firmly attached, nerve-connection by connective-tissue good.

Case 5.—White (pink eye) buck. Operated February 12th. Removed R. E. and reinserted it. No bandage applied. Eye somewhat bulging after operation.

Six hours: Cornea slightly hazy. T. — (slightly).

Second day: Cornea more hazy.

Fourth day: Cornea decidedly hazy. T. — 1.

Fifth day: Cornea still hazy, but yellow reflex can be seen from anterior chamber. T. — 1.

Seventh day: Cornea is now so opaque that contents of anterior chamber cannot be seen. Red rim appears around corneal margin. T. — 2.

Associated muscular action is present.

Twelfth day: Cornea rather less hazy than at last note, and yellowish body in anterior chamber can again be seen. Tension has improved somewhat and is now — 1. A few stitches still attached to conjunctiva were removed.

Eighteenth day: Cornea rather less hazy than before. T. — 1.

Twenty-third day: Cornea about same. Red vascular zone around margin of cornea has become very marked.

Twenty-fifth day: Cornea decidedly less hazy than it was, and is smooth. T. n. Cornea has remained insensitive. Other eye has not been implicated at any time. No rise of temperature nor apparent interference with the general health at any time.

Post-mortem examination: Eyeball found markedly atrophied, muscles firmly attached, also conjunctival sac; good vascularity. On section eyeball found to be disorganized, but no pus. Nerve-suture effected by plug of connective tissue.

Case 6.—Large gray, brown, and white buck. Operated February 13th. Removed R. E. and inserted R. E. of another rabbit of equal size. No bandage applied. Eyeball slightly bulging after the operation.

Six hours: Cornea slightly hazy.

Second day: T. — (slightly). Cornea is hazy, especially at central elliptical portion.

Third day: Cornea still more hazy. T. — 1.

Fourth day: Cornea begins to look sloughy and bulging, and considerable pus exudes from between eyelids. T. — 2.

Seventh day: Less suppuration of lids, but T. still — 2, and cornea still looks sloughy, especially at central portion.

Tenth day: Slight associated muscular action.

Fourteenth day: Cornea is becoming perforated and iris shows.

Fifteenth day: Contents of eyeball are escaping.

Sixteenth day: Contents of eyeball have escaped; opening in cornea covered over by a scab.

Twentieth day: Nothing remains but a small retracted stump.

Thirty-ninth day: Condition the same. Cornea has been insensitive. Other eye, temperature, and apparent general health have remained normal throughout.

Post-mortem examination: Stump remains; good muscular, connective-tissue, and vascular union between transplanted eyeball and conjunctival sac. Sutured ends of nerve connected by plug of connective tissue.

Case 7.—Small black and white buck. Operated February 14. Removed R. E. and inserted R. E. of another rabbit of equal size. No bandage applied.

Six hours: Cornea slightly hazy at periphery. T. n.

Second day: T. — (slightly).

Third day: Entire cornea hazy. T. — 2. Pus (apparently) in anterior chamber. Slight suppuration from lids.

Fourth day: Cornea more hazy, so that contents of anterior chamber cannot be seen. Slight associated muscular action.

Sixth day: Eyeball has diminished in size since operation. Cornea quite opaque. Sclera white and bloodless.

Eighth day: Cornea quite opaque, central elliptical portion especially.

Tenth day: Cornea looks sloughy. Pericorneal vascularity appears.

Eleventh day: Cornea is covered by a deposit of white material, which, when scraped off and examined microscopically, is found to consist of corneal epithelium and of pus-cells.

Twelfth day: White deposit on cornea has increased.

Thirteenth day: Perforation of cornea, and some of contents of eyeball have escaped.

Fourteenth day: Eyeball is now a suppurating mass.

Twentieth day: Suppuration has gradually ceased. There is now merely a small retracted stump remaining.

Twenty-fifth day: Cornea has remained insensitive throughout. Other eyeball has not become implicated at any time. There has been no rise of temperature or apparent interference with health at any time.

Case 8.—Medium-sized black doe. Operated February 16th. R. E. removed and R. E. of Case 9 inserted. Bandaged, but no chamois covering applied.

Second day: Bandage has become displaced and pressing upon side of eye causes it to bulge. Bandage removed. T. — 1. Cornea hazy.

Third day: Slight associated muscular action.

Fifth day: Cornea more hazy, especially at central elliptical portion.

Eighth day: Eyeball has atrophied some. Cornea opaque. T. — 1. Pericorneal vascularity appears.

Tenth day: Cornea of an opaque yellowish-white color. T. + .

Fifteenth day: Eyeball has gradually diminished in size and is now quite small.

Post-mortem examination: Eyeball half its original size. Good connective-tissue union of nerve to eyeball and of eyeball to conjunctival sac; vascular and muscular connections good.

Cornea has remained insensitive. Other eye has remained normal. There has been no elevation of temperature, nor apparent interference with general health at any time.

Case 9.—Large black buck. Operated February 16th. Removed R. E. and inserted R. E. of Case 8. Applied bandage but no chamois covering.

Second day: Bandage has become displaced, and eyeball is exposed. Bandage removed. Cornea hazy. T. — 1.

Third day: T. — 1. Cornea densely hazy. Considerable suppuration from lids. Slight ocular movements.

Fifth day: Cornea quite opaque and looks roughened, especially at central elliptical portion.

Eighth day: Cornea rather less opaque, but periphery has assumed a yellowish tint.

Tenth day: Red line can be seen around cornea, consisting of blood-vessels which have passed over from conjunctival sac. Tension more nearly normal. Eyeball has become rather smaller than on insertion.

Twelfth day: Excessive vascularity of conjunctiva immediately around cornea. Ocular movements good. T. — (slightly). Cornea opaque and slightly yellow peripherally.

Sixteenth day: T. n. Cornea somewhat bulging. Cornea smooth and still opaque, but yellow color has disappeared.

Twenty-fifth day: T. + (slightly). Cornea opaque, but less than before. Considerable atrophy of eyeball.

Twenty-eighth day: Cornea has remained insensitive.

Post-mortem examination shows atrophy of eyeball, connective-tissue union of sutured nerve-ends, and of globe with sac; good vascular and muscular connections.

Other eye has remained normal throughout, and there has been no elevation of temperature nor apparent interference with general health at any time.

Case 10.—Large white and black buck. Operated February 19th. Removed R. E. and reinserted it at end of fifteen minutes. Crinoline bandage and chamois covering applied.

Fifth day: Bandage has become displaced so that it constricts base of ears and has made them very sore, and must be removed. Dressings only very little soiled from discharges; these are sweet. One suture still in lid was removed. Cornea only slightly hazy; iris can be distinctly seen. T. n. Ocular movements good. Vascular zone around margin of cornea is seen. Bandage left off on account of soreness.

Sixth day: Cornea decidedly more hazy, especially at central elliptical portion. T. — (slightly).

Eighth day: Cornea now densely hazy. T. — .

Tenth day: Cornea now quite opaque, especially in centre. T. — .

Fifteenth day: Central portion of cornea is beginning to clear up some.

Twenty-second day: T. — 1. Cornea still opaque, especially at centre. Cornea has remained insensitive. There has been no implication of the other eye. Temperature and apparent general health have remained normal.

Post-mortem examination: Eyeball atrophied, much smaller than on insertion; muscles firmly attached; globe firmly united to conjunctival sac, and blood-vessels can be seen passing between the two. Seat of suture of optic nerve presents a firm connective-tissue connecting mass.

Case 11.—Small reddish-brown buck. Operated February 26th. Removed R. E. and inserted R. E. of another rabbit of about the same size. Bandaged and chamois covering.

Sixth day: Bandage has remained in position until to-day, when it has become displaced, and corner of eye is exposed and covered by a crust of desiccated discharge.

Eighth day: Discharges have stained chamois covering.

Sixteenth day: Removed bandage. Chamois had become very much stained with discharges. Anterior portion of eyeball has been exposed, the lids having been covered only by a scab for last ten days. Eyelids very much swollen. One stitch still in place and was removed. Cornea is hazy, of a bluish-white color, which is denser anteriorly where exposure took place. T. — (slightly). A few stitches remained in conjunctiva and were removed. Ocular movements good. Red vascular rim is seen around margin of cornea. Washed out thoroughly with solution of mercuric bichloride (1 to 10,000) and rebandaged.

Twenty-sixth day: Eyeball has become atrophied, and is much smaller than it was on insertion. Cornea is densely opaque. Post-mortem examination shows lens opaque and swollen, vitreous consisting of an opaque, starchy mass; optic nerve united to eyeball by connective tissue; globe firmly united to sac by connective tissue; muscles well attached; vascularity good. Cornea has remained insensitive. Other eye, temperature, and apparent health have remained unaffected.

Case 12.—Large grayish-brown buck. Operated February 28th. Removed R. E., and reimplanted it after ten minutes. Bandaged and chamois covering applied.

Fourth day: Bandage has been displaced, and inner canthus is exposed. Discharge shows through chamois. Nictitating membrane of other eye looks red and swollen, probably from pressure of bandage, which appears rather tight. No elevation of temperature or apparent interference with general health.

Seventh day: The red and swollen condition of the nictitating membrane of the sound eye continuing, bandage was removed; it seems to have been on very tightly, for base of both ears present numerous excoriations from pressure. On removal of bandage eyelids are very much swollen. One stitch remained in lid, and was removed. Nictitating membrane red and swollen. Cornea decidedly hazy, and this is especially marked internally, corresponding to the exposed portion from displacement of the bandage on the fourth day. T. — (slightly). Red vascular margin surrounds cornea. Ocular movements good. Bandage cannot be reapplied on account of extensive excoriations.

Eighth day: Sound eye appears normal to-day, and nictitating membrane is no longer red and swollen, showing this to have been produced by pressure from bandage. Nictitating membrane of reimplanted eye is also normal. Cornea rather denser, especially in centre. T. — 1.

Thirteenth day: Cornea still more dense, and central elliptical portion very opaque. Swelling of eyelids has disappeared.

Sixteenth day: Vascularity of peripheral portion of cornea is very marked, and rapidly extending toward centre. T. n.

Twenty-fourth day: Entire cornea now looks red and fleshy, excepting central elliptical portion, which is of a dense, yellowish-white color. T. n. or +.

Fortieth day: Entire cornea now looks fleshy; it has remained insensitive. Eyeball is considerably atrophied. T. + 1. Other eye has not been implicated. There has been no elevation of temperature or apparent interference with the general health at any time.

Case 13.—Medium-sized reddish-gray buck. Operated March 12th. Removed R. E. and reinserted it after ten minutes. Bandaged and chamois covering.

Ninth day: Bandage has become displaced and is coming off. On removing it, dressings found discolored with discharges, which are sweet. Considerable mucopurulent discharge, mixed with hair, on compress. Lids very œdematous and still closed by stitches, these were removed. Considerable discharge between lids, upon removing which cornea found opaque, of a bluish-white color, and covered by considerable desiccated discharge, which under the microscope is found to consist of pus, fat-globules, and corneal epithelium. T. — (slightly). Conformation of eyeball good. Vascularity around cornea apparent. Ocular movements good. Bandage could not be reapplied on account of numerous excoriations.

Fifteenth day: Cornea looks sloughy, especially at central elliptical portion.

Twenty-first day: Cornea looks sloughy and slightly bulging, as though about to rupture. T. — 1.

Post-mortem examination: Entire disorganization of interior of eyeball. Conjunctival sac and optic nerve present firm connective-tissue union. Muscles firmly attached. Vascularity of reimplanted eyeball good. Cornea has remained insensitive. There has been no implication of the other eye, and no rise of temperature or apparent interference with general health at any time.

Case 14.—White doe (pink eye). Operated March 3d. Removed R. E. and reimplanted it. Chills or convulsions during anæsthesia. Bandaged and covered with flannel.

Fourth day: Has displaced bandage so that eye is partly exposed. Hence dressing removed. Moderate amount of discharge upon compress. Lids very much swollen; stitches were still in place and were removed. Cornea is decidedly hazy. Nictitating membrane seems to have sloughed away. T. — (slightly).

Sixth day: Stitches in conjunctiva were removed. The bandage had been left off. Ocular movements good. T. — 1. Cornea more opaque and iris cannot be seen through it. Pericorneal vascularity present.

Tenth day: A portion of the cornea corresponding to the central elliptical portion has become dry and yellow; peripheral portion has cleared up some, and yellowish reflex is seen from within. T. — 1. Cornea has remained insensitive.

Post-mortem examination: Eyeball slightly atrophied; on section found to be disorganized; no pus. Nerve firmly united by connective tissue, also globe to conjunctival sac. Muscles firmly attached and vascularity of globe good. The other eye has remained unimplicated throughout, and there has been no elevation of temperature, no apparent interference with general health at any time.

Case 15.—Small black buck, broken leg. Operated March 4th. Removed R. E. and reimplanted it. Bandaged and covered with chamois.

Twelfth day: Discharge has soaked through chamois covering. Bandage removed. Dressings soaked through; discharges sweet. All sutures have come away. Eyelids slightly swollen. Cornea slightly hazy, but iris can be seen distinctly. T. n. Good ocular movements.

Vascular zone around edges of cornea. Washed out with bichloride solution (1 to 10,000) and rebandaged.

Nineteenth day: Removed bandage. Slight discharge between lids. Cornea slightly hazy; iris can still be seen distinctly. T. n. Washed out and rebandged.

Twenty-sixth day: Condition of eyeball the same as when last noted. Cornea has cleared up a very little. Washed out and rebandaged.

Thirty-sixth day: Condition of eyeball still as favorable as at last account. Conformation good. T. n. Cornea still hazy, but smooth. Iris can still be seen. Pericorneal vascularity excessive. Ocular movements good. The other eye has remained unimplicated. There has been no elevation of temperature nor apparent interference with general health at any time. Cornea of reimplanted eyeball has remained insensitive.

Case 16.—Half-grown black buck. Operated March 6th. Removed R. E. and inserted R. E. of another rabbit of equal size and age. Bandage and chamois applied.

Seventh day: Has succeeded in removing bandage entirely. There has been a moderate amount of discharge. Stitches in eyelids have come away. Cornea is smooth, hazy, but iris can be seen distinctly. T. n. Ocular movements good. Vascularity of pericorneal conjunctiva is good. Washed out and rebandaged.

Twentieth day: Chamois has not yet become discolored excepting by some discharge which had formed a crust at the anterior portion of the flannel bandage. Cotton compress is soaked through and has been displaced downward; there is considerable muco-purulent discharge between lids. Eyeball of good conformation. T. n. Cornea smooth, but hazy, of a bluish-white color, clearer in centre than at periphery, which latter portion is so dense that iris can hardly be seen through it. Cornea is surrounded by a vascular zone, consisting of blood-vessels passing over from the conjunctival sac. Washed out and rebandaged.

Twenty-fourth day: Bandage removed. Condition same. Washed out and reapplied bandage.

Thirty-fourth day: Bandage having become soiled was removed. T. n. Eyeball of good conformation. Cornea smooth, hazy, but slightly less than at last note, so that iris can be indistinctly seen. Cornea has remained insensitive. Other eye has remained unimplicated and there has been no elevation of temperature nor apparent interference with general health at any time.

Case 17.—Large white doe (pink eye). Operated March 6th. Removed R. E. and inserted R. E. of another rabbit of large size (blue-black iris). Bandage and chamois applied.

Fifth day: Everything has progressed favorably to date, the bandage having remained in place and not become soiled. To-day small vesicle appears on the nictitating membrane of the sound eye. There is no elevation of temperature nor interference with health. Bandage seems to be rather tight.

Eighth day: Vesicle has disappeared from nictitating membrane of other (sound) eye, but it is still reddened, and eyeball bulges somewhat, so that it is apparent bandage is on too tightly. Bandage has become displaced and inner canthus is exposed. Bandage removed. Lid very much reddened and œdematous and held together by stitches; the latter were removed. Moderate amount of discharge between edges of lids, is sweet. Cornea is quite hazy and iris cannot be seen. There is the usual vascular zone around margin of cornea. Ocular movements good. Bandage was not reapplied on account of soreness of surrounding parts.

Tenth day: Redness has disappeared from both eyes. Cornea has become still more hazy, especially at central elliptical portion.

Thirteenth day: Central portion of cornea looks sloughy. T. — 1. Rabbit has had litter of eight young.

Eighteenth day: Cornea beginning to slough. Coloring matter of iris appears through cornea.

Twentieth day: Contents of eyeball have escaped. There now remains only a suppurating stump.

Twenty-fourth day: There is now merely a good-sized stump, non-suppurating, retracted into posterior portion of orbit.

Thirty-fourth day: Condition the same. Cornea has remained insensitive throughout, and other eye, temperature, and apparent general health have remained normal (excepting affection as a result of pressure of bandage, noted on fifth and eighth days).

Case 18.—Large black doe, pregnant. Operated March 5th. Removed R. E. and inserted R. E. of another doe, similar size and color. Bandage and chamois applied.

Tenth day: Bandage has become displaced and anterior canthus is exposed. Dressing has become soaked through, and there is considerable discharge (sweet) upon compress and between edges of lids. Stitches have worked out. Cornea is decidedly hazy, so that iris cannot be seen through, and its surface is rough. Ocular movements good. There is vascularity surrounding the cornea. T. — 1. Rabbit is in labor; bandage left off.

Fifteenth day: Cornea looks sloughy, especially central portion.

Sixteenth day: Contents of eyeball have escaped through perforation of cornea.

Twenty-fifth day: Nothing remains but a small non-suppurating stump at back part of orbit.

Thirty-fifth day: Stump still remains. There has been no sensibility of cornea at any time, the sound eye has not been implicated, and there has been no elevation of temperature or apparent interference with general health.

Case 19.—White (pink eye) buck. Operated March 7th. Removed R. E. and inserted R. E. of Case 20. Bandage and chamois applied.

Third day: Since operation animal has not eaten, and bandage, which is on too tightly so that he cannot open his jaws, was removed. Discharge moderate. Eyelids very much swollen. Stitches in lids were removed. Cornea quite opaque, of a bluish-white color, and iris cannot be seen. T. — 1. Bandage not reapplied on account of extensive excoriations.

Fifth day: Cornea more dense and looks softened, especially in centre.

Tenth day: Central portion of cornea looks sloughy. T. — 2. Pericorneal conjunctiva is vascular. Ocular movements good.

Sixteenth day: Condition the same. Cornea still insensitive. Other eye has remained normal, and there has been no rise in temperature nor apparent deviation in general health at any time.

Post-mortem examination: Eyeball is smaller than on insertion, soft, and on section found to be disorganized. There is firm connective-tissue union between eyeball and nerve, and globe and conjunctival sac. Muscles are firmly attached and vascularity of globe is fair.

Case 20.—White and black buck. Operated March 7th. Removed R. E. and inserted R. E. of Case 19. Bandage and chamois applied.

Sixth day: Bandage, pressing hard against base of ears, and having produced numerous raw surfaces, was removed. Very little discharge. The sutures closing lids were removed. Cornea hazy, but iris can be seen, and in anterior chamber is seen yellowish body, such as was seen in the other two cases in which pink eyes were employed. T. — 1. Bandage not reapplied.

Tenth day: Cornea smooth, but densely opaque. T. — 2. Vascularity around cornea. Ocular movements established. Considerable discharge.

Twenty-third day: There has been no change in the condition of the transplanted eye. It is small, cornea smooth and opaque. T. — 2.

Thirty-third day: Since last note cornea has perforated and some of contents of eyeball have escaped. There is now a fair-sized, non-suppurating stump remaining. Transplanted cornea has not been sensitive at any

time. Other eye, temperature, and general health have remained normal.

Case 21.—Reddish-brown doe. Operated March 12th. Removed R. E. and inserted R. E. of Case 22. Bandage and chamois applied.

Fourteenth day: Bandage well in place, and neither chamois nor flannel has become soiled. On removing dressings, small amount of discharge upon compress—perfectly sweet. Eyelids but little changed from normal. Conformation of eyeball good. Cornea only slightly hazy, and brown iris can be seen distinctly through it. T. n. Ocular movements good. Pericorneal vascularity present. Washed out and rebandaged.

Eighteenth day: Condition the same.

Twenty-eighth day: Eyeball still looks as favorable as at last note. Cornea slightly hazy, and iris can be seen distinctly. Cornea has remained insensitive. T. n. Other eye has remained unimplicated. There has been no rise of temperature nor apparent deviation from the general health at any time.

Case 22.—Black buck. Operated March 12th. Removed R. E. and inserted R. E. of 21. Bandage and chamois applied.

Four and one-half days: Bandage still on and in place. No soaking of dressing. Discharge moderate and sweet. Eyelids still closed by sutures; these were removed. Ocular movement present. T. n.

Post-mortem examination: Eyeball about same size as when inserted. Conformation good. Muscles attached. Sac united to globe by connective-tissue fibres. Nerve attached to globe by thin strip of tissue, which under microscope is found to consist chiefly of small round cells (granulation tissue).

Case 23.—Black buck. Removed R. E. and inserted R. E. of 24. Operated March 19th. Bandage and chamois applied.

Seventh day: Bandage fairly in place. Moderate amount of muco-purulent discharge. Lids moderately swollen. Conformation and tension of eyeball good. Pericorneal vascularity exists. Ocular movements good. Cornea is smooth, hazy in greater part of its extent, but translucent and iris can be seen distinctly. At upper and outer portion is a small area, more densely opaque and slightly yellowish. Washed out and rebandaged.

Eleventh day: Condition same as at last record, except that zone of denser and yellowish infiltration has extended very slightly. T. n. Washed out and rebandaged.

Twenty-first day: Cornea is still hazy, but evenly so, and denser infiltration at upper and outer part has disappeared. T. n. Cornea still insensitive. Iris can still be seen. Other eye has remained normal throughout. There has been no rise of temperature nor apparent interference with the general health at any time.

Case 24.—Black and white buck. Operated March 19th. Removed R. E. and inserted R. E. of 23. There was considerable hemorrhage, and after trying to find optic nerve and failing for some time, operation was completed as in other cases, except that optic nerve was not sutured. Bandage and chamois applied.

Seventh day: Chamois covering in place and not soiled. Considerable discharge, so that cotton and flannel have become soaked through; discharge is sweet. One of stitches in lids still remaining was removed. Lids swollen. Cornea bluish-white and hazy, and along line of junction of lids is a line of denser opacity. Iris cannot be seen through cornea. T. —1. Conformation of eyeball good. Ocular movements good. Washed out and rebandaged.

Eleventh day: Cornea densely hazy, but smooth. T. —. Pericorneal vascularity is seen. Washed out and rebandaged.

Twenty-first day: Cornea has cleared up slightly, but iris still invisible. T. n. Conformation of eyeball good. Cornea still insensitive. Other eye has remained unimpaired. There has been no rise of temperature or interference with the general health at any time.

IV. Peculiarities and Management of the Rabbit when kept for Experimental Purposes.—This seems almost too simple a subject to command any space in an essay, and yet, since nothing has yet been written on these points, they cannot fail to be of service to future experimenters.

Rabbits are undoubtedly the most convenient animals to experiment upon, when a large number are required and a certain size is requisite. They are less delicate than is commonly supposed—not one of the thirty-five rabbits made use of by the writer suffered from sickness or died from illness. The darker shades—brown, gray, and black, and admixtures of these with white—are stronger and more hardy than are the pure white (pink eye) ones; but even the latter cannot be said to be delicate.

They bear ether very well—only three out of thirty-five died from the anæsthetic, and these deaths occurred among the first cases, while none occurred among the last twenty-five. The crying-out suddenly during anæsthesia should be taken as a danger-signal, and serve as a warning to discontinue the ether, even though the cornea be still sensitive, for this sign was noticed in the three fatal cases, and in one in which the animal stopped breathing but was resuscitated by artificial respiration. About two ounces of ether serve for one hour's anæsthesia, and air must be allowed them from time to time just as in man. Some cases were kept under ether for three hours with no bad effects.

They are kept most readily in wire coops of three or four stories, partitioned so as to have a size each of 15 by 24 by 15 inches, or by making five or six stories a great many can be kept in a small space; each such compartment will hold one or two animals—male and female go best together, but should be separated after the latter has become pregnant and the abdomen begins to enlarge; two bucks also go well together, but during the first twenty-four hours they are apt to fight—until one has ascertained the sex of the other, and no longer attempts to mount him; two does usually fight for a day or two, but then go well together. The wooden floor of the compartments should be covered with hay, and this should be changed at least every second or third day, the coops swept out thoroughly, and kept dry at all times.

The fæces, occurring in small, oval, hard pieces, and having but little smell, and the urine being small in amount and odorless, the abodes are very easily kept clean; and if this is done, two or three dozen animals can be kept, as directed above, without creating anything more than a faint odor; this constitutes a very important advantage when laboratories are situated in private houses; and for a practising physician it is very convenient to have this room under the same roof as his office.

Another advantage over dogs and cats is that they make very little noise; they have a peculiar habit of stamping with their hind legs without any apparent purpose, but they usually sleep at night, and even by day this stamping does not make sufficient noise to be heard much outside of the room.

They are more docile than dogs and cats, and defend themselves usually with their claws only, though sometimes a vicious one will be met with, and several scars on the writer's hands testify to the fact that they do bite; very little local and no constitutional inconvenience resulted from the bite, however.

The bucks have an ugly habit of passing their urine and whirling at the same time, so as to throw the stream outside of the coop; this is probably a provision of cleanliness, but the experimenter will hardly appreciate it if they perform this manœuvre, as they sometimes do, when he attempts to catch them; though being alkaline, it is unirritating, yet disagreeable, even when it happens to get into the eye.

They are rather more expensive than dogs or cats, costing $1.50 to $2 a pair (in the city), but they breed so quickly that this expense is materially diminished in a short time; their food costs less than would that of

canines. To feed thirty-five dogs would require considerable outlay, but with rabbits the cost is very moderate.

The best diet for them consists of a piece of carrot about the size of a goose's egg, a leaf of cabbage, and a handful of oats, twice a day; the refuse salads and greens may also be utilized as their food. They should have as much water as they will drink once a day; this is contrary to opinions in some works on zoölogy, but they always are greedy for water and thrive on it; this is probably because the vegetables they get while caged are drier than those they gather in the fields, and furthermore are destitute of the dew which probably furnishes them naturally with moisture. When fed more than twice a day, their fæces may become soft, and then smell horribly; hence this restriction in the way of feeding should be practised.

When the female is pregnant and the abdomen has increased in size, she should be isolated—put in a coop in the darkest part of the room; a small box, large enough to put her young in, should be placed in the coop; this she converts into a nest by arranging hay and the fur plucked from her breast in a circular manner. The duration of pregnancy is about five weeks, the number of young from four to eight, and labor lasts usually two or three hours; the doe is very little affected by it. When the place is too well lighted, or she is prevented from building her nest, or the surroundings are not to her liking, she kills the young by stamping upon them; when she preserves them they suckle three or four weeks and then shift for themselves. Even before lactation ceases the doe is ready for the buck, and thus litters succeed each other very rapidly.

Rabbits should be handled by the ears; and when their death is desired, a sharp blow against the back, while thus suspended, dislocates the cervical vertebræ, and kills them at once or very soon.

They are not as stupid as is commonly supposed, and by patting and stroking them they can be made to keep quiet for a change of dressing, when it would be impossible to hold them by force. When two are together one helps the other in trying to remove the bandages; or, should the wound be an open one, one rabbit is frequently seen licking the other's wounds, as was the case in the transplanted eyes when no bandage was applied.

NOTE.—The writer wishes to acknowledge his indebtedness to his friend, Dr. C. F. Mason, U. S. Army, to Dr. G. W. Vedder, and to his students, Messrs. Victoria, Clinton, Kemp, Michaelis, and Bartlett, for valuable assistance rendered in the performance of the series of operations.

[illegible] EAST FIFTY-EIGHTH STREET.

NITROUS OXIDE AS AN ANÆSTHETIC.—M. Laffont, in a recent communication to the Paris Société de Biologie, stated that nitrous oxide is a most dangerous anæsthetic. He has since further prosecuted his experiments; and, at a subsequent meeting, confirmed his previous statements. He has found proof that nitrous oxide is not an anæsthetic, but an asphyxiating agent, as MM. Jolyet and Blanche have proved. When this agent is used by dentists to produce anæsthesia, hyperglycæmia and glycosuria result. M. Laffont has verified these phenomena by personal experience. He has also ascertained that in animals these results take place before anæsthesia, during the period of deep breathing.

THE CLINICAL HISTORY of King Alfonso, of Spain, has recently been published by his physician, Dr. Tomás Santero, of Moreno. He regarded the anxiety and excitement aroused by the dispute with Germany over the Caroline Islands as the remote cause of the final outbreak of miliary tuberculosis which led to the king's death.

THE BILL separating the Massachusetts State Board of Health from the State Board of Lunacy and Charity has become a law.

THE TREATMENT OF ACNE.

BY MAHLON HUTCHINSON, A.B., M.D.,

[illegible]

MY attention was first called definitely to the use of the cold urethral sound in the treatment of acne by a short note in the *Journal of Cutaneous and Venereal Diseases* for November, 1884, referring to the success of its use in the hands of Dr. Sherwell, of Brooklyn, L. I. Previous to that time it had frequently occurred to me that great benefit might be derived from its use, but not possessing the courage gained from experience, and knowing the astonishment and repugnance that each and every patient would manifest—at least that I believed they would manifest—I had never put my theory to the test. I then believed, and still believe, that in ninety per cent. of cases of acne of all forms the exciting cause lies in the genito-urinary organs. Acne may be said to almost invariably manifest itself at the age of puberty, and this happens in such a large and overwhelming majority of cases that it must be considered more than a mere coincidence. I shall not attempt to explain how an irritation of the genital organs, due probably to hyperæmia, is reflected and manifests itself solely by an inflammation of the cutaneous, sebaceous glands; but very few physicians have not met with numerous instances of similar effects from similar seemingly remote causes. How many of us have not seen in children cases of partial paralysis of the lower extremities due to a redundant and tight prepuce? And when the simple operation was performed, how astonished the parents at the rapid recovery. The explanation of these effects can well be left to our pathologists, and of that I shall say nothing; but upon its practical bearing on our every-day experience I cannot insist too strongly.

Previous to November, 1884, I had borne in mind this cause—hyperæmia of the genital organs—and had treated all my cases of acne, with few exceptions, with potass. brom. and tr. gelsemii, accompanied by local applications of sapo viridis and ung. sulph. My success was moderate; but so moderate that the result was always doubtful, and my prognosis necessarily very guarded.

At this time I happened to have under treatment three cases of acne: Mr. Edward K——, acne pustulosa, very severe form; Mr. C. H. B——, acne papulosa et pustulosa, milder type; and Miss M. C. D——, acne papulosa, manifested chiefly by papules, with a few small pustules on forehead.[1] (These cases are fully reported hereafter.) I proposed to Messrs. K—— and B—— this method of treatment, explained to them my reasons for using the sound, and, both being sensible young men, they made no objection, but asserted that they would "do anything to get well." My success was startling even to myself, and I looked for the best results. In one week the improvement was very noticeable, and in six weeks I might have dismissed them cured to all external appearances. I, however, kept them under treatment for some two months; have frequently heard from and seen them since, and there has been no relapse.

In these cases, and, in fact, I may say, in all cases of acne, there is actually nothing to direct your attention to the genital organs. These two young men, Messrs. K—— and B——, would not acknowledge that they were of passionate natures, were not troubled with nocturnal emissions, had no fear of spermatorrhœa, and denied having ever practised masturbation or even having indulged in sexual intercourse. My experience has been that those much-to-be-pitied creatures with their nocturnal emissions, and their highly developed spermatophobia, suffer but little, if any, from acneiform eruptions. And *le raison d'être* is the nocturnal emissions. Let those

[1] I may here remark, that the type of [illegible] is, as a rule, much less severe than in the [illegible] pustulosa is frequently met with [illegible] papulosa, while [illegible] is the prevailing type in females. [illegible]

cease, and let the hyperæmia and irritability of the genital organs persist, and we shall find developed a most promising case of acne papulosa et pustulosa.

During the past twelve months I have treated nineteen cases of acne in the male and seven in the female. Fifteen of my male patients and six of my female have recovered completely; the other five for various reasons not continuing the treatment long enough to form an opinion of its success or failure. Thirteen out of the fifteen males were treated by the cold sound exclusively, I may say, of all other means, although I invariably give a placebo. My plan has been for the first three weeks to give some laxative preparation, accompanied by local applications of sap. vir., benzoin, and ung. sulph. The improvement, except in the mildest cases, is scarcely, if at all, perceptible. At the end of three weeks I propose the cold sound, and, after carefully and plainly explaining its action to patients, I have never yet met with a refusal to permit its use. One to two weeks only are needed to prove to them that I am right, and in from one to two months their skin will be free from acne, but with numerous scars left to remind them of the past.

And now for the treatment of acne in the female. The cold urethral sound would of course be useless, and its analogue, the uterine sound, would also for numerous reasons be out of the question, even if there were a probability of benefit to be derived from its use. But our object is to reduce the supposed hyperæmia and allay irritation, and this can be otherwise accomplished. All of our recent works on gynecology recommend most highly the hot-water treatment in all forms of inflammation of the uterus and its appendages. The hot douche, it is asserted, constringes the blood-vessels, reduces the hyperæmia, and produces an absorption of the products of the inflammation. If acne in the female is due to a hyperæmia and irritability of the uterine system, why will not hot water, in the form of douches, in like manner relieve this hyperæmia, and, ergo, cure the acne? It will, and it does. At least such has been my experience, and although my cases have numbered only seven, still six out of those seven have been successes, and that percentage of recoveries is much larger than other methods of treatment can claim.

This method of treatment by means of hot vaginal douches I have never seen nor heard mention of, and I believe I may lay claim to the originality, if any, in its use. I am satisfied beyond a doubt that it will be as successful in the treatment of acne in the female as the use of the cold sound has been in the male. The rationale and method may be explained to the mothers of the young-girl patients, and no feelings of modesty shocked by mentioning such matters to the patients themselves. It is easy of application, and not only accomplishes the object we seek, but also cleanses the vaginal passage. It may not be a generally known fact, but upon inquiry any physician can satisfy himself of its truth, that young maidens seldom, if ever, syringe the vagina. The natural secretions and the last few drops of the menstrual discharge, of a consequence, collect in the passage, and, if not unhealthy, this habit, to say the least, is uncleanly.

The following are examples of the cases referred to above, and it would be but needless repetition to report the complete list.

Case I.—Edward K——, American, aged twenty, single, clerk, applied for treatment for acne on September 30, 1884. Face was greatly disfigured, and almost covered with large acne pustules and numerous cicatrices, the results of former pustules. Habits perfectly regular, digestion good, bowels normal. Patient was placed on potass. br., grs. xx., tr. gelsemii, gtt. v., t.i.d., with directions to wash face with sapo viridis twice a week.

October 30th.—The bromide has been increased to grs. xxx., t.i.d., but with little, if any, benefit. Passed No. 14 Am. cold sound, finding great irritability of the urethra, the pain being almost unbearable as the sound entered the bladder.

November 1st.—Passed sound again, producing somewhat less pain.

November 4th.—Passed sound, a slight improvement being now manifested in the appearance of the acne.

November 7th.—Passed sound.

November 10th.—Passed sound. Great improvement is now noticeable; no new pustules having formed, and the old ones drying up.

From November 10, 1884, to January 12, 1885, the cold sound was passed twice a week, the eruption completely disappearing on December 11th; and on January 12th Mr. K—— was dismissed, with the caution, however, to continue the use of the sound for a month or so longer once a week. On September 7, 1885, Mr. K—— called on me for some advice relative to other matters, and his face was then clear of blotch or pimple, and, according to his statement, had remained so since his last visit on January 12th. He was not then using the sound, and had not been for the past six months.

Case II.—C. H. B——, American, aged nineteen, single, printer, visited me first October 4, 1884. Patient had been afflicted with acne vulgaris for four years, the eruption being situated on face—forehead and cheeks; consists principally of papules, with a few moderately sized pustules. No bad habits, digestion good, bowels regular. Treatment: Determined to try in this case arsenic, and put patient upon liq. potass. arsenitis, gtt. v., t.i.d., with external applications of sapo viridis.

October 30th.—Fowler's solution has been gradually increased until now patient is taking gtt. x., t.i.d. Some improvement is noticeable, but the arsenic disagreeing with his stomach, it was discontinued. Passed No. 15 sound, finding a very sensitive urethra, especially the prostatic portion.

November 30th.—Sound has been passed every other day since last date. Improvement was manifest after the third passage, and to-day patient is dismissed with no papules nor pustules, and only a few red blotches, reminders of his past troubles. Cautioned to use the sound twice a week for two months.

March 2, 1885.—Patient called, stating that he had had no relapse, and the appearance of his face affirmed the truth of his statement.

Case III.—Miss M. C. D——, American, aged eighteen, student, applied for treatment for acne papulosa October 16, 1884. The eruption situated chiefly on forehead, with a few papules on cheeks. General health good, bowels slightly constipated. Menstrual function regular, but considerable pain during first day of flow. Treatment: Externally, sapo viridis twice a week; also face-wash of tincture of benzoin simp., ℥ ss., aqua, ℥ j. Internally, a laxative, consisting of magnes. sulph., ferri sulph., and acid. sulph.

November 15th.—Improvement can be seen from past month's treatment, but not very great. Explained to the young lady's mother my theory of the cause of the disease, and advised hot-water vaginal douches every other night.

December 1st.—Quite an improvement manifest, and but few papules left. Hot-water douches twice a week.

January 2, 1885.—Has not had the sign of a pimple for past week. Hot-water douches once a week.

January 30th.—Dismissed patient, but advised that the douches be continued indefinitely once a week.

Case IV.—Miss G. B——, American, aged twenty, was sent to me from Colorado for treatment for acne papulosa. She visited me first on September 4, 1885. Her eruption was very similar to that mentioned in Case III., and the treatment instituted was the same, with this exception, however, that the hot-water vaginal douches were used from the first. Miss B—— remained in Chicago two weeks, when she returned to her home. The improvement had by that time commenced, and I considered it unnecessary for her to remain here. She

continued to use the hot douches up to October 26th, when she wrote me that the eruption had about disappeared. On November 26th she again wrote, stating that she had had no acne for two weeks, having used the hot-water douches twice a week since last date.

January 14, 1886.—A letter received from Miss B. informs me that her improvement has remained constant, with no relapse.

Case V.—Benj. E. L——, American, aged twenty-[illegible], single, painter, applied on September 5, 1885, for treatment for one of the worst cases of acne pustulosa it had ever been my fortune to meet with. Where there were no pustules on his face there were large, deep scars, and the man's life was a burden to him. The pustules were in some instances so large that they constituted veritable boils, and gave rise to considerable pain. General health perfect. I put him upon potass. br. and gelsemium, with local treatment of sapo viridis and acid carbolic.

September 28th.—Very little improvement. Passed cold sound No. 14, Am., finding the urethra very sensitive, especially the prostatic portion.

October 5th.—Great improvement already manifest, the sound having been passed three times only.

November 3d.—Very much improved. No pustules remaining, and only some indurations from former pustules. The cold sound has been passed every third day during past month, and the passage now gives rise to no pain.

December 1st.—No pustules remaining. Three or four indurated nodules. Dismissed patient, but ordered the use of the sound once a week for two months.

January 11, 1886.—Patient calls to exhibit his face and show me how well it has kept.

In conclusion, I may state that in the mild forms of acne, acne punctata, etc., local medication, accompanied by the internal exhibition of arsenic br., is sometimes sufficient for a cure; but in the twenty-five cases above referred to I have excluded these mild types, of which I have had during the past year under treatment probably a dozen. As adjuvants to the cold sound and hot-water treatments I have used the following prescriptions, but have derived but little, if any, benefit from them when used alone:

℞. Tr. benzoin simp..... ℥ ss.
Aquæ..... ℥ j.
M. Sig.—Face-wash.

℞. Sap. viridis..... ℥ viij.
Aq. cologn..... ℥ iv.
Solve et filtra. Sig.—To be used as cleansing face-wash.

℞. Sulphur precip..... ℥ ij.
Ung. vaselin..... ℥ vij.
M. Sig.—Apply once a day.

The above is a useful ointment, more useful, however, in acne rosacea than in acne vulgaris.

As a laxative mixture the following:

℞. Ferri sulph..... gr. xv.
Acid. sulph. dil..... ♏ ijss.
Magnes. sulph..... ℥ ij.
Aquæ.....ad ℥ vj.
M. Sig.—Two drachms half an hour before breakfast in half a glass of water.

Arsenic given in the following form is sometimes quite efficacious:

℞. Sol. arsen. br. (Clemens)..... ♏ ij.
Aquæ.....ad ℥ iv.
M. Sig.—One drachm t.i.d., gradually increased to two drachms t.i.d.

[illegible] Opera House, Chicago, Ill.

THERAPEUTICS OF AMENORRHŒA.[1]

By H. L. BOLDT, M.D.,

[illegible]

When the invitation was extended to me by your chairman to read a paper on amenorrhœa before this Section I felt very much at loss as to what I should write, because the subject in consideration has been so often written upon by able authorities that there is really very little or nothing left for one to do. It can, therefore, hardly be expected that I should give new ideas, nor will it be possible to give the subject a full consideration in such a short paper. I will, therefore, only state the general management of such cases which has proved itself most successful in my hands.

It is not within the scope of this paper to consider the pathological conditions productive of amenorrhœa any further than becomes absolutely necessary in the consideration of the treatment, as a full paper on the subject would be out of place before this Section.

Amenorrhœa, then, from physiological causes, as pregnancy, nursing, etc., also the amenorrhœa dependent on non-development or imperfect development of the organs of generation, and those cases requiring surgical interference will not be considered by me. It is my object to consider this symptom, for such it only is, in that class of patients where the physiological process of menstruation had been fully established, and then through some cause has been partially or entirely suppressed, from reasons which are not physiological; and those cases where the age of puberty has arrived, the organs of generation present, the monthly period wanting, and this absent physiological symptom giving rise to morbid symptoms.

Predominant of the class of patients who present themselves to the practitioner are young women between the ages of sixteen and twenty years, who will tell us that they have menstruated a certain number of times quite regularly up to within four months or a year ago, that then menstruation either ceased entirely or became more and more scanty until complete suppression was present. A large proportion of this class have only had a slight show now and then. The symptomatology of this class of patients usually is: that they are suffering from headaches, a tired sensation in all their limbs, in fact a general languor, loss of appetite, constipation, cardiac palpitation on the least exertion, and some occasionally even without any physical exercise, etc.

On looking at them we find these girls pale and poorly nourished; their muscles are flabby, the mucous membrane of the lips and eyelids colorless. Physical examination frequently reveals the characteristic anæmic murmurs, heart-sounds feeble, but sometimes somewhat accentuated, when at the time of examination they are afflicted with the symptom of palpitation. In some cases the face and lower extremities are œdematous and the abdomen bloated.

These patients present, then, either a well-marked example of anæmia or chlorosis, and they are usually under the impression that it is only the absence of the monthly period which causes their condition, seldom entertaining the idea that the latter symptom is dependent on their general condition.

Now in this class of patients it becomes our duty not to give emmenagogues, for these I believe are very rarely to be given in amenorrhœa with the expectation of deriving any benefit, except in a form of cases as will hereafter be described, but to improve their general condition.

We find that the majority of these patients belong to one of two classes of society—the young ladies whose sole occupation is study or reading romance, with little or no healthy exercise; their diet consisting of dainties, they never can (?) eat a substantial and nourishing

[1] Read before the New York [illegible] Section on Materia Medica and Therapeutics, [illegible]

meal—they are the college students or the young ladies of society.

The second class, who have the same disorder, are the shop and factory girls, those whose occupation is also sedentary, and the food they eat inadequate to nourish the body. It may seem strange that I should separate these two classes of patients, who both present the same symptoms, dependent on the same cause, but it will be obvious to all that the patients of the latter class, who are compelled by circumstances to earn their maintenance with the needle or some similar sedentary occupation, cannot afford the same treatment which the other class can usually do, and which is generally put down in the books for patients suffering with amenorrhœa.

To effectually treat the first class of patients, they must at once be compelled to abandon their previous routine of living; they must have fresh air, exercise, and the proper food to bring about an equilibrium between mind and body. During the spring, summer, and autumn months a healthy, non-malarial country residence I consider most suitable for the majority of these cases. The exercise must positively be very guarded in the beginning; the body being in a state of starvation, the muscular structure is very flaccid, and immoderate exercise under such conditions is liable to bring about accidents to the pelvic organs which would be equally serious, if not more so, than the primary ailment. Hence I consider the much-lauded horseback exercise, which many authors recommend in their writings, frequently without giving the proper precautions, so that many whose experience has not taught them otherwise may be led to prescribe it indiscriminately, not only erroneous but dangerous in the commencement of the treatment, as is also the case with *long* walks. Any exercise, if not previously considered with the existing physical condition, and the amount to be taken told to the patient, may result in a flexion or a version of the uterus, with perhaps subsequent congestion or inflammation of this organ; besides, pathological conditions of the adnexa may result in addition.

The amount of exercise must be increased later to suit the condition of the patient. I consider a slow walk of from fifteen to twenty minutes' duration, several times daily, quite sufficient in the beginning.

A sponge-bath with salt water, night and morning, rubbing the skin briskly with a coarse towel, so as to establish the circulation more thoroughly, thereby bringing about tissue changes, has been universally recommended by me as an adjunct, with the exception of a few days before the expected menstrual flow, if this is known; never have I seen harm result from it. A few days before the expected flow, the patient should enjoy more rest, and a hot foot and sitz-bath is then used once daily. The clothing must be warm—flannel being worn next to the skin, and the foot-wear equal to the rest of the wearing-apparel.

The diet should consist mainly of milk, oat-meal, hens' eggs, and rare beef, given in small quantities but frequently repeated, according to the condition of the stomach—a glass of good Hungarian wine or Dublin stout, two or three times daily, with the meals. Among the vegetables, those containing iron in proportionately large quantity are selected, as beans, peas, lentils, etc. For the past two years Murdock's liquid food was used with benefit, if it could be retained on the stomach, but many patients are unable to take it because it produces such an effect, on account of the peculiar odor and taste. Bovinine is an artificial food which seems to take the place of the Murdock's food very well, and it does not possess the disagreeable properties; but as to its full utility I am not yet able to speak.

After each meal from a half to one hour's rest in the recumbent position should be enjoined.

For the torpidity of the bowels it is necessary to impress on each individual that a regular hour must be kept, whether or not a desire to go to stool is present; then a careful but complete massage of the abdomen twice daily, each kneading from fifteen to thirty minutes duration; for this purpose I have found Dr. Butler's electro-magnetic machine to answer admirably. In some cases where this treatment does not suffice, a pill containing ¼ gr. ex. nux vomica, ½ gr. aloïn, 2 gr. compound ex. colocynth, and half a grain of ex. belladonna, night and morning, has given much satisfaction.

The second class of patients in this variety take a walk early in the morning before going to work, also when through with their sedentary occupation in the evening. Gymnastic exercise for five minutes thrice daily, in the beginning, gradually increasing the amount to fifteen or twenty minutes three times per day. Instead of the expensive wine, they are ordered a glass of ale and porter, or beer, with their meals, which seems to increase the appetite in many cases. A small quantity of raw beef (two ounces), chopped fine and seasoned to suit the taste, is given three times daily, in addition to the other food, provided the stomach does not rebel against it—the beef containing more iron than any other variety of meat. Cake, pie, etc., is stopped entirely. At the time of the expected catamenia they stop the gymnastic exercise and their walks, and are kept in the recumbent position as much as possible during their free time. In other respects, the same treatment as for the first class is ordered.

We know from competent observers that iron is necessary to the formation of hæmoglobin and red blood-corpuscles, and that the diseases, anæmia and chlorosis, are dependent on changes in the blood. In each the proportion of red blood-corpuscles is diminished. We also know that the functional activity of iron takes place in the blood.

The interesting observations of Rabuteau and others, which show the change in the quantity of red blood-corpuscles under the influence of this remedy in these diseases, prove that it is absolutely necessary for this class of patients to get iron in some form. Yet it must be remembered that occasionally we meet with a patient who cannot take a certain preparation. Hence it is necessary when we meet with a case of this unusual idiosyncrasy, to search over the long list of preparations until the one is found which can be taken. The citrate of iron with quinia answers in the majority of cases, and has the advantage that the small quantity of quinia therein contained acts somewhat as an appetizer.

Iron is, consequently, *the* remedy which is invariably used in one or the other form. I will put myself down on the list with those, however, who insist that it should be used in small doses, the larger doses being apt to produce gastric disturbance by mechanical irritation. Frequently have I observed patients who did not improve, but on the contrary got worse, that is, they developed intestinal disturbance, while taking large doses, from twenty to thirty drops, of the muriate tincture of iron, and these same patients being ordered four to five drops of the same food, for as such we must consider it, when used with a view of abating the pathological condition present in these cachexias, rapidly improve. Of course, whatever gastro-intestinal disturbance is present must be first overcome by suitable means.

In phthisical patients, when amenorrhœa is present, which usually causes much alarm, it is well to impress upon them very strongly that the absence of menstruation need not cause the least disquiet, and by giving treatment directed to the pulmonary disorder, in addition to such general treatment as may be indicated and already spoken of before, we can occasionally succeed to re-establish the function for a longer or shorter time, and no doubt the patients often feel better for it.

In the amenorrhœa frequently present in plethoric patients, I find the dietetic treatment for the plethora, daily baths, plenty of methodical exercise, and the use of electricity, to be of the best service. The variety of electricity, whether faradic or galvanic, or whether the positive

or negative pole is used interiorly, is probably immaterial, although one case where faradism alone had been used unsuccessfully for two months was finally cured by the adjuvant of the constant current. The case was as follows: A lady, aged thirty, began to menstruate at sixteen years; married when twenty years of age; no children; she had always been regular up to twenty-four years of age, the flow lasting four days. About this age she began to get very fat, so that her weight increased from one hundred and forty pounds to two hundred and ten pounds within two years; the latter weight continued nearly the same up to the time when I saw her. She had a slight show regularly every four weeks, when presenting herself to me, but its duration was only from two hours to a half day, very light color, watery, as she called it. The absence of the regular menstruation produced several unpleasant symptoms.

Permanganate of potass was given in one-grain doses after meals during the interval, and one week prior to the expected flow the dose was increased to six grains daily, with a warm sitz-bath at bedtime. The treatment had the desired effect of producing a flow of two and a half days' duration. At the next period, the treatment produced no effect. Then faradism was used, beginning three days before the expected catamenia, the negative pole in the uterus, and the positive pole over the region of the uterus and ovaries (my abdominal electrode is four inches wide, by thirteen inches long, thereby the whole hypogastric and ovarian regions are taken in by one electrode); the current used was as strong as could possibly be borne by the patient, the sittings being twenty minutes in duration. No change was produced. The next month the same treatment was instituted with like result. On the next occasion the galvanic current was used, interiorly the anode and externally the cathode, with the satisfactory result of producing a flow three days in duration; and the following month the same treatment increased the menstrual discharge to four days' duration. For three months I was enabled to keep the patient under observation without further treatment than the general hygienic and dietetic which had been instituted from the beginning, after the potash treatment was found to fail, with the information that the flow had been regular and normal in quantity and quality, and that the former inconvenient symptoms had abated.

As a rule, however, the result is not so satisfactory in amenorrhœa occurring in this class of patients.

Another variety of patients are those who, during the menstrual flow, are affected by some sudden grief, joy, or domestic disaster—in short, some emotional disturbance causes the sudden cessation of the monthly period.

In this form, I think, the treatment is, as a rule, effectual, if the patient applies early and the proper advice is given and obeyed. It is that three days before the next expected epoch the patient keeps perfectly quiet—in bed, if possible—the application of hot-water bags to the lumbar and hypogastric regions, and a hot foot-bath with a small quantity of English mustard in the water, once or twice daily, the bath of from fifteen to twenty minutes' duration. The patient then goes to bed again, and is covered with warm blankets so as to produce perspiration. Emmenagogues may be used, but they are usually superfluous. Frequently the flow may be brought on again by this procedure during the same period, if the patient applies for aid at that time. It is, of course, necessary, if possible, to overcome the emotional cause. The same treatment also holds good if the catamenia is suddenly suppressed by exposure.

In a limited number of cases these means are ineffectual; then a course should be pursued, consisting of massage, warm general baths, etc., and one of the emmenagogues—preferably permanganate of potash.

Another variety of patients of whom I shall speak are those in whom the menses have become suppressed under the influence of sea-air, and I know of no more effectual remedy for this than the last-named emmenagogue, as I have already stated in my report on this remedy at the last meeting. The manner in which it is used was also spoken of at that time.

The last form of cases which come under consideration, are those of whom I spoke previously, as having arrived at the age of puberty, the patients strong and healthy in appearance, the organs of generation appreciably well developed, nothing present which would require surgical interference, and the very scanty or non-appearance of the flow causing a series of uncomfortable symptoms. For these patients electricity and massage, together with an occasional warm bath, have been generally successful.

Clinical Department.

SUBCUTANEOUS USE OF MORPHINE IN INFANTILE CONVULSIONS.

Dr. C. S. Scofield, of Boston, reports the case of a child eighteen months of age, previously healthy, whom he had been called to see on account of eclampsia. The child had been in convulsions for two hours and had been given emetics, hot baths, and mustard to the feet, without any benefit. The writer at once administered one-eighth grain of sulphate of morphine hypodermatically, which was repeated at the end of twenty minutes—no effect having been produced by the first dose. This was also followed by no improvement, and a third injection was administered twenty minutes later. This was effectual in controlling the convulsions, and by the expiration of an hour from the time of administration of the first dose the child was sleeping quietly. When seen the following morning the child had taken food as usual, and was apparently as well as ever.

ABSENCE OF ONE KIDNEY AND CARCINOMA OF THE OTHER IN A CHILD THREE MONTHS OLD.

Dr. J. W. Wood, of Port Richmond, S. I., writes that he was called to see a little girl three months old, suffering from diarrhœa. He prescribed paregoric and castor oil; the next day the child was much better, and he did not see her again for ten days. At that time he was again called and told that the little patient had not passed water for two days. The child was evidently in pain, alternately crying and dozing, the features were pinched, the pulse very rapid, but the temperature normal. The abdomen was greatly distended, the superficial veins were prominent and somewhat varicose. An attempt at catheterization was made, but was unsuccessful owing to the fact that the meatus urinarius was much higher up in the vagina than normal. Hot applications over the abbomen were ordered, but no urine was passed. The child failed gradually and died three days later, having had complete suppression of urine for five days. The autopsy was made twenty-four hours later by the writer and Dr. John Wilson. The abdominal swelling had subsided. Upon opening the abdomen about a gill of serum was found. The spleen was normal. The left kidney was absent. On the right side was found a large firm mass, binding down the intestines, which upon removal was seen to be an enlarged and cancerous kidney. Its length was five inches, its other diameters three inches. The ureter was enormously dilated, and was seven inches in length. The bladder was hypertrophied, contracted, and empty. Dr. Wood says that he has been able to find records of only fifty cases of single kidney, but in view of the fact that operations for the removal of a diseased kidney are becoming more frequent he would advise the catheterization of the ureters in every instance as a preliminary measure.

ESCAPE OF A BILIARY CALCULUS THROUGH THE ABDOMINAL WALL.

Dr. J. W. Kales, of Franklinville, N.Y., relates the following case: The patient was a woman about fifty years of age, married, and very fleshy. About three years ago an abscess formed in the right hypochondrium, which finally opened and dischaged a large amount of pus. A fistula was formed and small quantities of pus drained away, for a year or more, at which time the patient came under the writer's immediate charge. Various expedients were tried to cause the fistula to close. The external orifice of the fistula contracted; but no progress toward a permanent cure was made. After some delay the orifice was enlarged with a knife in order that the discharge might escape more readily. Pus continued to flow from the orifice for two or three months; but as all propositions of treatment were refused by the patient, nature was allowed to take her course. Finally, after a night of intense suffering a biliary calculus was discharged. The fistula immediately closed, and the patient, for the past six months, has enjoyed better health than for a number of years. The calculus was enveloped in a layer of inspissated bile, was ovoid, about three-fourths of an inch in length, one-half an inch in diameter, and weighed, after desiccation, forty-two grains. The calculus had evidently ulcerated its way out of the gall-bladder through the abdominal parietes.

URINARY CALCULUS SLOUGHED OUT THROUGH THE PERINEUM.

Dr. W. T. Cheatham, of Henderson, N. C., writes: "A negro man brought me a urinary calculus of phosphatic composition, weighing five hundred and twenty grains, about the size and shape of a pullet's egg, the small end terminating in a neck-like extension one-fourth of an inch in diameter, and one-half an inch long. He represented it as having fallen from his little step-son's privates while walking across the floor about two hours previously. I immediately repaired to his place of residence, where I found a boy of eight years standing by the fire, eating, and manifesting little concern about his condition. He was a typical subject of the calculous diathesis—emaciated, cachectic, dwarfish—his corporal development not exceeding that of an average healthy child of two years. An examination revealed the following condition: A portion of the perineum, the entire scrotum, and both testes had been completely swept away by the destructive inflammation and sloughing consequent upon the passage of the stone from the bladder to the outer world. The penis had suffered almost annihilation; its connections to the rami of the ossa pubis and ischia were nearly severed, being attached by a narrow strip of integument, the body of the organ for three-fourths of its length being absent, and the prostate gland with its urethral connections sharing a similar fate. The index finger was passed into the bladder through the opening made by the passage of the calculus. Its mucous coating was found thickened and morbidly sensitive, giving some pain while passing the finger over its surface in search of concretions, none of which were found to exist, nature having rid that organ of its only specimen. Under the influence of strict cleanliness of the parts and of a tonic internally, the wound healed well, a bougie being left *in situ* to prevent extravasation of the urine. The boy was seen some months later, and it was found that the external opening had closed from neglect to pass the bougie, resulting in urinary infiltration to the extent of complete anasarca. Pulse feeble and 160; respiration labored, with a preternatural disposition to sleep. The opening was restored, about an ounce of urine escaping. Numerous small punctures were made with the point of a lancet over the body, buttocks, and thighs, from which the infiltrated urine freely escaped, emitting an ammoniacal odor. A cathartic dose of bi-tartrate of potash was administered, and directions given to let me know the day following if he was living. No message was received. Eight days subsequently, while on a visit to a patient in the same neighborhood, learning that the child was living, I called to see him. No sloughing had taken place, only a few of the punctures presenting an unhealthy condition. Prescribed a tonic, and ordered that the small sores be kept clean with a carbolized wash. I never saw him again, but learn that he died the summer following of acute dysentery. His early history was obscured by the ignorance of his parents, but I am informed that he inherited the diathesis, his father having died of gravel. His mother and step-father thought his trouble commenced when he was eighteen months old, as he suffered pain at that time, and ever after had a difficulty in passing his urine until the passage of the stone. I am of opinion, from the peculiar formation and the composition of the calculus, that it originated in the prostatic portion of the urethra, and its growth by accretion forced its vesical extremity into the bladder before the sloughing process occurred, which led to its extrusion from the body."

Progress of Medical Science.

Varicosities of the Lingual Vein as a Prognostic Sign.—G. Cecil Dickson, writing in the *British Medical Journal* says, that under certain conditions, especially in elderly persons, the ranine and lingual veins become remarkably dilated and varicose; often they are much enlarged and present many bulgings, which extend in a racemose manner to the edge of the tongue. From observation he believes that this condition indicates important changes in the circulatory system. In two cases in which this condition was marked, both patients eventually had cerebral hemorrhages. The lingual vein, being a branch of the internal jugular, will indicate a state of the blood-current in this vein, and thus show the condition of the entire intracranial venous system. Distentions and varicosities of the lingual will thus become associated with passive congestion in the brain sinuses, and thus point out the diseases that are liable to occur when this condition is present.

Expulsion of a Tape-worm by the Mouth.—Dr. E. Martel reports in the *Gazette des Hôpitaux* the following rare case: A lady, eighty-six years of age, who had for two years been taking scraped raw beef, experienced a slight indigestion one day after taking a glass of milk followed by a little red wine. During the vomiting which ensued she felt something strange in her mouth which she easily pulled out but could not determine its nature, as she was nearly blind. It proved to be a tænia twenty-six inches long, two-fifths inch wide at one end, and one-twelfth inch at the other. Three days later the patient passed from the rectum a worm forty-seven inches long, and a third fragment, twenty-four inches long, was passed the same way the following day.

Boracic Acid in Diabetes Mellitus.—Mr. F. A. Monckton reports a case of a boy, aged fourteen, suffering from diabetes mellitus, with all the symptoms in an aggravated form, who was apparently cured by the use of boracic acid in seven-grain doses three times daily. At first there were no stringent dietary regulations, and even in the latter part of the treatment only sugar, potatoes, and oatmeal were forbidden. Bread was eaten at the meals in the ordinary way. He gradually gained in weight, his health improved, and the sugar disappeared from the urine.—*Therapeutic Gazette* Jan. 15, 1886.

The Therapeutics of Hydrophobia.—Mr. William Curran, writing in the *Medical Press and Circular* on this subject, gives a list of some two hundred preparations which have been advocated at different times as curative of rabies.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, May 29, 1886.

A REVIEW OF SOME NEW REMEDIES.

AN occasional review of the numerous new remedies which are being poured upon the profession by industrious clinicians and enterprising pharmacists may not be without interest to our readers. A well-known European firm has recently sent out a description of some of these drugs, and, with some additions and more subtractions, it forms the basis of the following summary:

Absynthin is the bitter principle of *artemesia ab sinthium*. It is soluble in alcohol, but not in water. Given in doses of 0.1 to 0.25, twice daily, Roux has found it a good stomachic, improving the appetite and relieving constipation in persons who are chlorotic and in convalescents.

Sclerotinic acid, as prepared by Podwyssotsky, is a brownish powder obtained from secale cornutum. It keeps well, and in this respect is superior to ergot, whose therapeutic properties it represents. It is said to produce uterine contractions, and is a good hæmostatic. Bourneville has shown it to have no value in epilepsy. It may be given subcutaneously in doses of from 0.03 to 0.10.

Aseptol (formula, $C_6H_5OHSO_3OH$) is a 33½ per cent. solution of orthoxyphenolsulfate. It is recommended as a substitute for phenol and salicylic acid, whose antiseptic properties it possesses without being poisonous or irritating. It is soluble in water, alcohol, and glycerine. On account of its non-irritating properties it is said to be useful in ophthalmological practice. It is antiseptic in solutions of 0.1 per cent.

Boldin is a substance obtained from the leaves of *boldoa fragrans*, a non-deciduous plant growing in Bolivia and Chili. The alkaloid boldin is recommended to be used in cases of gall-stones and in bladder catarrh. It is also said to have hypnotic properties.

Hippurate of lime is a white salt, soluble in water, and is given in doses of 0.6. Poulet has recommended it in phosphaturia, and a number of writers have used it successfully in scrofula.

Cannabinon, dose 0.5 to 1.0 gm., and cannabin tannicum, dose the same, are preparations obtained from cannabis indica, and having an uncertain hypnotic power.

Cotoin verum ($C_{22}H_{18}O_6$) is a substance obtained from coto bark. The preparations of this bark have obtained considerable reputation in the treatment of diarrhœa, especially in marasmic states. Cotoin verum is soluble in alcohol and alkaline solutions, and is given in doses of 1.00 to adults and 0.05 to children.

Colchicein, from colchicin, the alkaloid of colchicum, has yet to be tried, we believe, in gout and rheumatism. The dose would be 0.001 to 0.002 gm.

Hazeline, from the bark of *hamamelis virginica*, is regarded as having some astringent and hæmostatic properties.

Helenin ($C_{12}H_{10}O$) is a kind of camphor, soluble in alcohol. It is strongly antiseptic, 1 part to 10,000 preventing decomposition of urine. Korab has used it in tuberculosis, malaria, and in diarrhœa. Valenzuela has used it in pertussis and bronchitis. Obiol has used it internally and externally in diphtheria. The dose is 0.01 to 0.03.

Osmiate of potassium ($K_2O_2 \cdot OsO_2 \cdot 2H_2O$) is recommended instead of osmic acid in neuralgia and epilepsy, and as a parenchymatous injection in goitres, lymphomata, and sarcomata. Internally it may be given in doses of 0.001 to 0.015 daily in the form of pills.

Naphthaline is a drug whose properties have been fully described in these columns. Its value in diarrhœa and in typhoid fever as a disinfectant of the intestinal tract is established. The drug is insoluble in water or alcohol, and is given in doses of 1 to 5 gms. daily.

Pyridin (C_5H_5N), a colorless, peculiar smelling drug, is used in the form of vapor for the relief of asthma. A teaspoonful may be poured in an open dish and allowed to stand in the room, and the patient breathes the vapor for twenty to thirty minutes.

Terpinhydrat and terebrine are substances just now much vaunted in the treatment of chronic bronchitis. Terpine is also used in chronic nephritis, in doses of 0.2 to 0.4 gm.

Salol is a compound obtained from phenol and salicylic acid, and it is claimed by Sahli to be superior to salicylic acid as an anti-rheumatic. It may be given in the same doses as salicylate of sodium, and although large amounts make the urine dark, the drug is said to have no toxic effect.

Hypnone and urethan are drugs which have been quite recently described in THE RECORD. Hypnone, dose ♏ iij. to vj., does not seem to be a very certain or agreeable medicine, but urethan, dose 1 gm., is recommended as a safe, fairly trustworthy, and not disagreeable hypnotic.

In the foregoing list we find that a number of alleged active principles have been obtained, and their use is recommended in place of the crude drug. So far as this can be safely done it means an advance in therapeutics, because it gives more accuracy and certainty to prescribing. Some of the other drugs may prove useful, but we find none which seem likely to create an epoch in therapeutics.

FURTHER PROGRESS IN BACTERIOTHERAPY.

SINCE Cantani published an account of his first experiment in bacteriotherapy about a year ago, reports have appeared in the journals from time to time of other attempts in the same direction, some of which seemed to be moderately successful, while others were apparent failures. The best of these, or at least the one related with the least apparent bias on one side or the other,

is that of Dr. Luigi de Blasi in the *Giornale Internazionale delle Scienze Mediche*, No. 3, 1886. Dr. de Blasi reports eight cases of well-developed pulmonary phthisis, treated during January and February of the present year, by inhalations of pure cultures of bacterium termo, unaided by arsenic, cod-liver oil, or any other form of internal medication. The inhalations were given by means of a steam atomizer, about six drachms (twenty-five cubic centimetres) of the culture-fluid being consumed at each inhalation during a period of five minutes. The results obtained in the eight cases may be summarized as follows:

In none of the cases did the inhalations, repeated twice a day and occupying five minutes each time, produce the slightest inconvenience. There was neither nausea, vomiting, nor cough.

In every instance the tubercle bacilli in the sputum were reduced in number, but in none of the cases did they wholly disappear. In one, however, after a gradual diminution, the bacilli suddenly reappeared in great numbers without any apparent cause.

In all the bacterium termo was increased in quantity during the continuance of the inhalations. The microorganism was found in small numbers in the sputum, however, in every case even before treatment was begun.

In six cases the cough became less troublesome, and the expectoration was decreased in amount, although it preserved its muco-purulent character.

An increase of weight was observed in two cases, two of the patients lost flesh steadily, and in the remaining four no change was observed in this respect.

The fever was not lessened in a single case. As to the objective symptoms, there was not only no improvement, but there was even a deterioration in nearly every instance.

Six of the patients stated that they felt stronger and better while taking the inhalations.

This can hardly be said to make a very favorable showing for bacteriotherapy, although it is not sufficiently discouraging to condemn the method as utterly worthless. The experiments were conducted during the least favorable season of the year, when even at Palermo the weather is changeable and trying to invalids. Furthermore, the trials were made purely to determine the absolute value of the bacterium termo as a destroyer of the tubercle bacillus, and other therapeutic measures, whose efficacy is undoubted, were ignored in order not to vitiate the experiments.

Dr. de Blasi found by researches in the laboratory that cod-liver oil, Fowler's solution, quinine, salicylic acid, antipyrine, and various other drugs used in phthisis did not destroy the vitality of the bacterium termo, which preserved its power of reproduction when these agents were added in varying proportions to the culture-fluid. These substances would therefore not be incompatible with the bacterium termo, but would rather better the chances of success by improving nutrition, and enabling the patient to hold every point that was gained through the agency of the inhalations.

Fanciful as this method may seem, we do not feel ready yet to chant its requiem, but still less are we prepared to welcome it as a potent remedy for phthisis until it can point to much better results than it has yet been able to do.

THE RELATION BETWEEN RHEUMATISM AND CHOREA.

Although less frequent mention is made of rheumatism among the etiological factors in the production of chorea now than in former years, there are still many, especially among the French and English writers, who regard it as of considerable causative moment.

In a recent monograph, reprinted from the *Berliner klinische Wochenschrift*, Dr. J. Prior attempts to prove that the relationship supposed to exist between these two affections is a purely imaginary one. After reviewing and comparing the mass of statistics collated by preceding writers, he adduces the results of a study of upward of one hundred cases observed by himself. In 94.5 per cent. of the cases of chorea there was neither history of previous rheumatic affection nor any signs of valvular trouble in the heart. Four of the patients gave evidences of old cardiac disease, and one had had pains in the right hand and fingers, possibly rheumatic, two weeks before the choreic symptoms were manifested. This author concludes, therefore, from his studies, that the coexistence of endocarditis and chorea is of too frequent occurrence to be regarded as anything more than a coincidence. Furthermore, chorea occurs with greater frequency before the fifteenth year of life, while rheumatism is less common at this period than later. Chorea also attacks girls by preference, and rheumatism, while by no means sparing females, is met with rather more often in males.

In seeking for the etiological factors in any given disease negative facts are often of even greater value than positive ones, and a few sets of figures showing the nonexistence of a certain supposed cause will offset a much larger number on the other side seemingly giving support to such a relationship. And this is the case, we believe, with regard to chorea, and it is more than probable that rheumatism is of little or no moment in the production of the disease. The evidence that embolism is a cause is equally insufficient, and we are forced to content ourselves, in the present state of our knowledge, in regarding chorea as one of the pure neuroses, dependent upon no ascertainable anatomical lesion.

DR. HOLMES IN ENGLAND.

It is a just source of gratification and pride to the American profession that Dr. Holmes should be received with so much warmth and hospitality during his present visit to England. Dr. Holmes, while more a man of letters than of medicine, has nevertheless always continued closely associated in work and sympathy with our profession, and has done perhaps more than any other to give an intellectual and literary status to us upon this side of the water. American medicine therefore takes to itself some of the honors that are being paid to her distinguished representative now in England.

The occasion is aptly seized by *The Lancet* to lament the decline in literary talent and culture, and in social standing, among doctors of the present day. Dr. Holmes will leave no successor, nor are there many even of the scholarly type which he represents. The rage to-day is for something practical, for skill in technique, and we are indifferent to the graces of scholarship or to an adornment of sound learning. We forget that, after all, "The

One Hoss Shay" will live longer than Virchow's "Geschwülste."

Yet perhaps our contemporary is a little pessimistic. We would be more positive if it unfortunately had not illustrated its point by the painfully inelegant English of "welcoming him *in our midst*." We live, however, in the belief that the rank and file of doctors are better now than they used to be, and if we have not a second Holmes, perhaps there may yet in coming years be raised up someone worthy to be ranked with him.

THE EXTINCTION OF GOITRE.

Dr. William Webb recently read a paper before the Midland Branch of the British Medical Association "Upon the Derbyshire Neck," in which he advances the opinion that enlargement of the thyroid gland is a disease which, under the modifying influences of an advancing civilization, will become extinct. Goitre is occasioned, he says, by increased function of the thyroid gland, which causes a true hypertrophy of it. Upon the theory that the natural function of the thyroid is to supplement an impeded respiration, such as would occur during sleep, during pregnancy, while carrying heavy burdens, or when suffering from any other mechanical restraint, he bases his interpretation of the occurrence of goitre in Derbyshire. The girl approaching womanhood works for her bread in the Derbyshire cotton mills, walking several miles over steep hills before six o'clock in the morning to her work, lives in a feculent atmosphere, works ten hours a day, and tramps back to her home at night. Goitre is common among those who are deprived of nourishing food and among those who intermarry. It is not confined to those who drink water of any special character.

In closing the paper the writer states that goitre is much less prevalent than it was thirty years ago, and yet the miners drink the same water. They get better wages, which means more nutritious food. The railway connects the goitrous districts with adjacent towns, so that the people travel more, see more, and intermarry much less than formerly. If the decrease of goitre continues in the same ratio as in the last generation, endemic goitre will soon disappear from Derbyshire.

A PROPOSED "PASTEUR INSTITUTE" IN NEW YORK CITY.

The project of establishing an institute in this city for the treatment of persons bitten by mad dogs seems to be seriously agitated. We learn that Dr. Valentine Mott has brought over from Paris a rabbit inoculated by Pasteur. This rabbit died on May 16th, and another one inoculated from it died on May 24th, and inoculations are to be continued *secundum artem*. The proposed "Pasteur Institute" is reported to be already organized, and an appeal to the public for $5,000 is to be made. It would be only just, both to the public and the medical profession, that some authentic information be furnished as to how well qualified the gentlemen composing this organization are to carry out their purpose. The technique, as is well known, is difficult, and involves a thorough knowledge of all Pasteur's views and methods of work, as well as no inconsiderable amount of time.

It was authoritatively stated a short time ago, that Pasteur was for the present unwilling to have any other institute established than that in Paris. Considering all this, and the fact that the prophylactic value of the method is still not demonstrated, it would be well for the organizers of the "Institute" to give some more definite assurances as to their capacities and purpose.

THE DISINFECTION OF RAGS.

The disinfection of rags is now claiming a great deal of public attention. The principal reason for this appears to be a difference of opinion between the rag importers and the health authorities as to what is necessary in the premises. The special committee of the Chamber of Commerce appointed to investigate the matter have been taking testimony *pro* and *con*, with the promise that some definite conclusions will eventually be reached. A similar inquiry is being carried on in Boston with a like end in view. The necessity for this is becoming more apparent as the present methods of rag disinfection are impartially scrutinized.

So far it is quite apparent that there has been manifested an inordinate zeal on the part of the health authorities to prove that superheated steam is the best, if not the only, disinfectant for the purposes named. Resolutions of sanitary conventions to this effect have been repeatedly published, and strenuous efforts have been made to create public opinion in its favor. Curiously enough most of this work has been done by a very few gentlemen, who have, all other things being equal, shown a great interest in guarding the public health. Without attempting to associate cause and effect, it has been shown that all these efforts have culminated in the employment of a patented process for applying the steam. It is unfortunate, to say the least, that such coincidences should be the basis of a charge of interested motives on the part of some of the parties concerned. This is to be deplored, as all such measures intended for the protection of the health of the people should be above suspicion. It is not, however, our purpose at present to discuss this part of the question. Scientifically we can view the present method of steam disinfection from the standpoint of its utility. In so doing it will be well to consider certain facts which are well established in the history of epidemics, and which have not been shaken by any evidence brought out in the investigations now being carried on.

Disinfection in the bale, as at present adopted, is of no use. It is impossible by merely thrusting a perforated screw into a bale to force steam equably and effectively into every portion of it.

This has been illustrated by a very interesting and conclusive experiment tried in Boston. The importers caused to be introduced into different portions of bales when originally packed for importation, self-registering thermometers. These bales were afterward subjected to the steam disinfection at the port of entry, which was Boston, and the results as shown on the thermometers were carefully noted, giving a range from 212° F., in one instance, down to 85° F., the average being 109° F.

Such a temperature, if it accomplished anything, would be in favor of propagating the disease-germs rather than

of destroying them. Yet, as we understand it, this is the method so strenuously advocated by the signers of resolutions, and so persistently enforced by the health authorities of New York, Boston, and Philadelphia.

It may be proper, in this connection, to consider the fact that no one has been able to produce an authenticated case of cholera coming from rags, a fortunate circumstance, in view of the inefficient method of disinfection.

Disinfection by any process to be thorough requires the unbaling of rags. Practically this is impossible at the port of entry. Aside from other considerations the cost would be too great. But it is recommended, and justly too, to admit rags from countries not affected with contagious diseases, and in cases of suspicion or doubt to disinfect the exterior of the bales before unloading, and that when the rags are unbaled at the mills they shall be properly disinfected under the supervision of the local health authorities.

This would make the local authorities responsible, and if a case of contagious disease broke out in a paper-making town, the responsibility would be fixed upon an officer on the spot, who could at once apply a remedy.

By the present system, it is almost impossible to fix the blame in case of the appearance of contagious diseases.

The health officers at the several ports of entry through which rags were coming to the mill would disown the responsibility.

Again, it is a curious fact that there is no case on record of a contagious disease being started in a paper-mill by foreign rags. On the other hand, there are numerous instances in which disease, such, for example, as small-pox, has been traced to domestic rags, which are not subject to any disinfection. If, however, disinfection were carried on in the proper towns, it would be much easier for the health boards to protect their towns against the entry of disease in this way.

These measures could not fail to prove satisfactory to all concerned, and be ample protection for the people in all cases of doubt. Superheated steam when proprerly used might accomplish this, but as at present employed it is utterly worthless.

Another Pathological Laboratory to be Built.—We learn that Dr. C. N. Hoagland, of Brooklyn, who is a member of the Board of Regents of the Long Island College Hospital, will soon begin the erection of a laboratory on Henry Street, directly opposite the hospital. It will be known as the Hoagland Laboratory of the Long Island College Hospital, and will be planned after the general style of the Carnegie Laboratory, on Twenty-sixth Street, in this city. In addition to its medical and scientific departments the laboratory will contain a library and a museum. The students of the Long Island College Hospital are to have free access to the new building.

Several Sewers in Detroit have been choked up all winter by the hulls of vessels lying up against them.

The Best Thing yet discovered for sea-sickness is port.

News of the Week.

The Ohio State Medical Society will hold its forty-first annual meeting at Akron, O., on June 2, 3, and 4, 1886.

Dr. Frank Donaldson, Jr., of Baltimore, was the author of the paper on the pneumatic cabinet before the Climatological Association, and not Dr. Donaldson, Sr., as stated.

Death of M. Legrand du Saulle.—Legal and mental medicine has sustained a severe loss in the death of M. Legrand du Saulle, physician to La Salpêtrière. His death occurred on May 6th, in the fifty-sixth year of his age. The deceased was author of a large number of works and monographs, and had just completed a systematic treatise on Legal Medicine and Toxicology.

Pasteur's Inoculations up to May 4th had reached the number of 950, with 6 deaths.

The Philadelphia County Medical Society and The American Medical Association.—At a special meeting of this Society, May 18th, the following resolutions were adopted by a *viva voce* vote:

"*Resolved*, That the Philadelphia County Medical Society has learned with surprise of the action of the American Medical Association at St. Louis in excluding the duly elected delegates from this Society.

Resolved, That, as the subject has been referred back to this Society for final action, the legality of said election is hereby reaffirmed, and that while it would be perfectly right for the delegates to vindicate the validity of their election by a resort to legal measures, yet, in the interest of peace, such action is not urged.

Resolved, That in excluding the delegates from this Society the Judicial Council have violated the plain rules of evidence and of justice.

Dr. William T. Corlett.—In a valuable article in The Medical Record of April 17th, on the "Bromide of Arsenic in Skin Disease," the author's name was given incorrectly as Corbett, instead of Corlett.

A Safe and Sure Hypnotic, according to Dr. K. Gunzberg, of Moscow, is chloral hydrate in doses of one gramme, given diluted per anum.

A King who Believes in Antiseptics.—The King of Servia, according to the journals, has issued the following: "Whereas it is irrefutably proved by science that the so-called antiseptic treatment of wounds yields more beneficial results than all other methods, we are pleased to order that henceforward the said antiseptic plan of treatment be solely employed in all the hospitals of our kingdom, and that corrosive sublimate and iodoform be used until our further disposition."

Queen Margarita, of Italy, has selected for her physician Signora Margarita Farne. This lady was one of the first Italian women who studied medicine, having commenced her course in 1870. She has practised in several hospitals in Turin and Milan.

Professor Bingham's Resignation.—An emergency meeting of the Trustees of the Vermont University was held May 20th. After a heated debate lasting six hours,

Dr. L. M. Bingham, the Professor of Surgery, for whose dismissal the students struck, offered his resignation, which was accepted.

THE COCAINE HABIT.—No drug with so short a history has gotten hold of so many victims as cocaine. We fear that the cocaine habit has a great and gloomy future before it. It is a habit more easily acquired and one which ruins body and mind even more quickly than does morphine. We make these comments *a propos* of a shocking case recently reported in a city in Central New York. A physician and his daughter were reported to have gone to a hotel and there have exhibited almost maniacal symptoms from the effects of cocaine. Both had been taking it in immense doses subcutaneously for some time.

AN ATTACK ON THE BUREAU OF ANIMAL INDUSTRY.—Representative Dr. John Swinburne, of New York, recently made a report attacking the Bureau of Animal Industry, his main point being apparently that said Bureau advocates the extinction of pleuro-pneumonia by slaughtering animals. If this is his only objection Representative Swinburne had much better keep quiet. If there is one thing upon which intelligent breeders and veterinarians are agreed it is that pleuro-pneumonia must be stamped out, and that it cannot be quarantined or inoculated out of existence.

THE NEW YORK MEDICAL MONTHLY is another candidate for journalistic favors, and comes to us in its first issue full of promise. It is edited by Dr. J. Leonard Corning, of this city, who will doubtless prove his fitness to conduct a journal. Among the promised contributors to it are many of the leading medical men of this town. The present issue contains practical articles by Drs. Otis, Agnew, Fox, and Schweig. We welcome it to our table.

THE LATEST SUMMARY OF PASTEUR'S WORK.—Up to April 14th, Pasteur had inoculated 688 persons, presumably bitten by mad dogs, with only one death. He had also inoculated 19 Russians bitten by a mad wolf. Of these nineteen, three have died from hydrophobia—about sixteen per cent. The usual per cent. of deaths from the bites of mad wolves is said to be about sixty-seven. Since April 14th, Pasteur has treated other Russians bitten by mad wolves and mad dogs. One of the former recently died from the effects of his wounds; one of the latter from hydrophobia, after having been submitted to treatment. This makes in all 720 cases treated, with a total of five deaths from rabies, despite treatment. Pasteur has found that the rabies resulting from wolf bites is the same as that of dogs, and only more dangerous, because the bites of wolves are more numerous and severe.

"THE OTHER SIDE OF COCAINE—THE BAD SIDE," was the subject of a paper presented by Dr. A. W. Calhoun, of this city, to the State Medical Association, in Augusta, last week. The doctor argues strongly against the use of cocaine in cataract operations by extraction. He stated that before he began the use of cocaine from ninety-five to ninety-seven per cent. of all cataract operations by extraction proved successful, and that in a large number in which cocaine had been used he had bad results. He has abandoned its use altogether in operations by extraction.—*Atlanta Medical and Surgical Journal.*

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 24, 1886.

DANIEL LEWIS, M.D., PRESIDENT, IN THE CHAIR.

DISEASE OF THE EAR IN CHILDHOOD.

DR. E. BENJAMIN RAMSDELL said that in preparing this paper he did so, not with the hope of offering anything new to the specialist, but to call attention of the profession, especially of the general practitioner, to the importance of early recognition and treatment of disease of the ear in childhood. The importance of disease of the ear was manifest from a brief review of the anatomical relations of that organ. The middle ear was by far the most frequently affected. Out of 383 cases of disease of the ear in children under fourteen years of age which had come under his observation at the Manhattan Eye and Ear Hospital, 346 were affections of the middle ear. Only one per cent. of the entire number were cases of disease of the internal ear and auditory nerve. In general we could divide disease of the middle ear into suppurative and non-suppurative cases. The diagnosis of suppuration of the middle ear could be made almost from the presence of a purulent discharge, for out of 227 cases of discharge from the ear, in only three was the source of the discharge situated in the external auditory canal.

Proceeding to clean out the ear, the physician would find perforation of the tympanum and a suppurative periostitis, the inflammation having crept up the Eustachian tube from a catarrh in the naso-pharynx.

The treatment should consist in cleansing the ear, the use of the hot douche, the use of a few drops of peroxide of hydrogen, dusting with iodoform or borax, solution of nitrate of silver or other astringent applications, inflation, treatment of the naso-pharyngeal catarrh. Dr. Ramsdell employed water of a temperature of 120° F. By the time it had passed through the syringe and reached the ear the temperature would have decreased to a degree to be comfortable to the patient. A fountain syringe, and not a glass or Davidson, should be employed. Dr. Dayton had had considerable experience with cleansing the ear with a few drops of a ten per cent. solution of peroxide of hydrogen, and believed it to be a very efficacious method. It was followed by the use of soft absorbent cotton. Dr. Ramsdell related the histories of a number of cases illustrating the efficacy of treatment, both in suppurative otitis media and in catarrhal inflammation, whether acute, subacute, or chronic. Cleanliness and not drugs was all important in the treatment of suppurative inflammations of the middle ear. A thick discharge in many instances would resist the syringe, and necessitate careful cleansing with the cotton-holder. Sometimes syringing of the ear might cause continued inflammation, some of the water being retained and acting as a poultice. Gentle inflation aided in cleansing the ear. First cleanse, then dry, and follow by the application of a healing, non-irritating powder in such a way that it would lay upon the surface in a thin film. Where there existed fine granulations or polypi to keep up the discharge indefinitely, it was necessary to effect their removal—the poylypi by the curette, and the granulations by astringents. In cases of acute catarrh of the ear the hot douche followed by gentle inflation was very beneficial. In the chronic and subacute forms it was very necessary to cleanse and make use of healing applications to the naso-pharynx, which was always the seat of catarrhal process. The glycerite of tannin, applied on the cotton-probe, was beneficial. The cases related were those of patients seen in private practice, and in nearly or quite all there had been healing of the drumhead, with relief to hearing.

Dr. D. B. St. John Roosa thought that this direct and simple statement of Dr. Ramsdell's practice in acute aural disease in children had not only received the respectful attention of the Society to-night, but that it would also receive the consideration of the profession as it might be presented to them through the press. He would that there were an Emmet or a Sims, or some one of the character and ability of Emmet and Sims, to impress the American people with the fact that diseases of the ear were almost as dangerous as diseases of the womb. The profession was lulled to sleep in the matter of diseases of the ear in childhood by the incontestable truth that a large percentage of the acute aural troubles in children got well in spite of the fact that they received either no treatment at all, or that which was utterly without intelligence. But there was a contingent—a fearful contingent—which went on to chronic suppuration, bad hearing, and, in some instances, to facial paralysis. There would be very little difference of opinion among those who had had experience in the treatment of these cases respecting the propriety of the treatment laid down by the author. The variations in the treatment would be insignificant. The principle of cleanliness and appropriate astringents and attention to the naso-pharynx would remain. There was a practice, formerly coming from the homœopathic schools, in which the treatment was largely by drugs internally administered. That practice had not the advantage, which was sometimes claimed for it, of being modern. It was as old as Hahnemann. He thought that the opinion expressed to-night that disease of the ear was chiefly local was strikingly true. And while every practitioner might watch the skin, the bowels, the ventilation, etc., yet most of the treatment would be local.

Dr. O. D. Pomeroy thought the speakers had been a little hard on the general practitioner. The ravages resulting from otitis in children were not always susceptible of being arrested. Statistics showed that many cases of deaf-mutism were due to scarlet fever, and all knew that otitis media occurring during this disease often destroyed the hearing in an extremely short time, and was not always susceptible of being arrested by treatment, especially after the period when the physician's attention had been called to it. Again, examination of the drum-cavity and drum-membrane in a child was a difficult thing, and it was nothing short of a fine art to treat certain cases of otitis in children as they should be treated. Dr. Pomeroy spoke of a method of gaining entrance to the middle ear and of establishing drainage by inserting a rubber tube on a probe; withdrawing the probe, the tube drew up into the canal. It was rarely necessary to open the mastoid in children, but when necessary it could be done by firm pressure with a knife. The danger to life in children from ear disease was much less than in adults in proportion to the severity of the disease. It was often impossible to recognize disease of the ear in young children. It was a good rule whenever a child complained of pain without apparent cause to examine the ear and see if the cause did not lie there.

The President asked whether there was not something which would take the place of iodoform in the treatment of disease of the ear. It was our duty, he thought, to make the treatment of disease as agreeable as possible. Iodoform was disagreeable to both the patient and his friends.

Dr. Simon Baruch had recently made it a rule in scarlet fever to pull the little patient's ears, and try to detect the first symptom of disease. He thought the reason why the general practitioner overlooked these cases was that the disease developed at a period when the child was better and the physician had either relaxed his efforts or ceased his visits.

Dr. David Webster, in answer to some questions by the President, said he used water for injection of a temperature comfortable to the hand, or as warm as the patient would bear it. He thought boracic acid was as good as iodoform, and it had not the disagreeable odor of the latter.

Dr. Joseph Andrews advised against iodoform in acute otitis, and also in chronic cases. It was irritating and insoluble, as was also tannic acid. Boracic acid was better.

Dr. Garrish spoke from the standpoint of the general practitioner. He thought it important to pay attention to the general condition, and as so many patients were scrofulous, to give constitutional treatment. Poultices did much to relieve pain, but it was also necessary often to employ tincture of opium in sweet oil. He advised also the application of leeches in the neighborhood of the ear.

Dr. Laurence Johnson said he was one of the general practitioners who a year or so ago heard the voice crying in the wilderness, had given heed thereto, and gone to the specialist to learn what he should do to help diminish the unfavorable statistics pertaining to ear disease. He was able to testify to the benefit to be derived from following such advice as had been given in the paper of the evening. He gave instructions to the nurses in a certain institution in which there were cases of suppurative ear trouble not of an acute character, to cleanse the ears with the warm-water douche. The nurses who had charge of the girls followed his instructions, and every patient showed improvement after the treatment. As to the boys, his advice was not followed, and they all remained in the condition they were. In the early stage of acute otitis media he employed douches, leeches, and allayed pain by two or three grains of morphine to a drachm of glycerine. He thought injury resulted from continuing the douche too long It should not be repeated as long as the boracic acid remained dry.

Dr. Leszynsky related some cases in which the patients complained of symptoms not at all referable to the ear, and in which the ear trouble was not suspected until after the discharge took place. Here the attending physician could not be blamed for not recognizing the ear disease early.

Dr. Messenger thought a good deal depended upon the constitutional treatment, especially the diet. If children were properly fed on proper food they would get well of almost any disease. He approved of the hot douche and of hot poultices. He regarded iodoform as worse than useless; in fact he did not believe it was good for anything in any disease except to stink, and he had never known its odor to be destroyed. Cocaine in the adult had lessened the pain in the ear, and had done good. Rubbing the skin, and keeping it clean seemed to renew the life of children.

Dr. Holcombe had been amazed at the success of the author in healing the drumhead after it had been opened by suppurative inflammation. He thought much harm resulted from too often syringing the ear in these attacks. The Politzer method was also capable of being dangerous. He exhibited a rubber tube consisting of two parts united by a glass tube, which he used for sucking out the purulent matter. The glass portion enabled one to see his danger before drawing the pus into the mouth. He then applied a weak solution of borax.

Dr. Ramsdell closed the discussion, and said he thought a thin film of iodoform blown upon the diseased surface of the ear resulted in benefit, and could not cause irritation or prevent exit of the discharge. As to the healing of drumheads, he had even seen them grow up, as it were, in chronic cases in which there was what was called the cicatricial drumhead.

The Society adjourned until the fourth Monday in September.

A Bill to regulate the practice of veterinary medicine and surgery has recently been defeated in the Ohio House of Representatives.

STATE SANITARY CONVENTION,

UNDER THE AUSPICES OF THE PENNSYLVANIA STATE BOARD OF HEALTH,

Held in McCauli's Opera House, Philadelphia, May 12, 13, and 14, 1886.

WEDNESDAY, MAY 12TH—FIRST DAY.

THE President, WILLIAM PEPPER, M.D., LL.D., opened the session and introduced Robert E. Pattison, Governor of Pennsylvania, who delivered an address calling attention to the importance of such conventions, and the necessity for education of the public as to the importance of sanitary measures.

DR. BENJAMIN LEE, Secretary, Pennsylvania State Board of Health, read a paper on

AN EPIDEMIC OF DIPHTHERIA TRACED TO ITS SOURCE.

The epidemic referred to occurred in Pittsburg in the fall of 1877, affecting that portion of the city known as the "south side." This portion of the town is built on a flat and on a hill rising rapidly behind it. In the lower portion the sewer had but little fall, and as a result became filled to a large extent with filth. The sewer extending up the hill acted as a ventilator, carrying the offensive gases to the houses on the elevated portion. Many of the houses were entirely without traps. Immediately preceding the outbreak there were several heavy showers, filling the sewers and causing the forcing of sewer-gas into the houses. The disease developed and was most marked in the houses connected with this sewer.

REV. G. D. STROUD thought that the sewer system should be done away with, and earth-closets and destruction of foul matters by fire.

Dr. Carl H. Horsh read a paper insisting upon the necessity of physical education.

DR. HENRY F. FORMAD, of Philadelphia, read a paper on

TESTS FOR ORGANIC IMPURITIES IN WATER.

The influence of the water upon the health of the community is one of the best indications of its purity. After referring to the difficulties and objections pertaining to chemical tests—these are only quantitative, and give no information as to the character of the organic matter—the presence of bacteria in water was then spoken of. The number of bacteria is an indication of the quantity of organic matter present. The test which he recommended was the use of culture substances, a few drops of water being added to the sterilized albumen, and the quantity of organic matter estimated by the rapidity of the development of the bacteria. In reply to a question, Dr. Formad stated that it was probable that injurious organic matters might be present without the presence of bacteria.

DR. F. S. WILSON, Lazaretto Physician, read a paper on

THE IMPORTATION OF FOREIGN RAGS.

This question calls for attention at this time. If we accept the germ theory of disease, old rags afford an excellent culture substance for these germs. In order to avoid danger from this source, he recommended that no rags be admitted without they had been thoroughly disinfected before shipment; or, what he thought better, the rags should be reduced to pulp before shipment.

DR. WM. TAYLOR, Health Commissioner of Boston, stated that in Boston no rags were admitted without being subjected to disinfection in the port of Boston, under the supervision of the Board of Health. The method found most satisfactory was that by superheated steam. This process is insisted upon even where a certificate of disinfection accompanies the cargo.

DR. A. N. BELL, of New York, considered rags the most dangerous of all articles of commerce. Up to recent times rags were considered so foul that it was not worth while to try to disinfect them. It has been asserted by those interested that rags never produced any diseases, and that the rags were cleaned before being shipped. The first process to which rags are subjected is that of cleaning, in which fifteen per cent. of the weight is lost. The ships may become the carriers of disease and may contaminate the cargo, so that rags which have been disinfected before shipment may again become infected. He advocated the use of superheated steam as a means of disinfection. Dr. Bell offered a resolution, which was adopted, that the Convention indorse the plan adopted by the Board of Health of Boston, and recommend its adoption by other ports.

Dr. D. W. Jeffries, of Chester, Pa., read a paper on

THE HEATING AND VENTILATION OF PUBLIC SCHOOL BUILDINGS.

Dr. Albert L. Gihon, Medical Director of the U. S. Navy, read a paper on

ECONOMIC SANITATION.

Dr. J. Lowry Sibbett, of Carlisle, Pa., read a paper on

NARCOTIC APPETITES.

DR. LAWRENCE WOLFF, of Philadelphia, delivered an address on

OUR DRUGS AND MEDICINES.

His examinations led him to believe that, as a rule, the drugs manufactured in this country were pure. The handling of drugs should be entirely restricted to physicians and druggists. As a rule, the accusations made against druggists were shown to be unfounded.

EVENING SESSION.

Hon. Erastus Brooks, of West New Brighton, N. Y., read the first annual address, on

THE OBLIGATION OF STATES AND CITIES

to preserve the health of the people.

THURSDAY, MAY 13TH—SECOND DAY—MORNING SESSION.

The first paper was by DR. FRANK WOODBURY, of Philadelphia, on

PHYSIC-TIPPLING AND MEDICINE-BIBBING.

He referred to the rapid increase in the consumption of such drugs as the bromides, chloral, opium, etc. It is said that of chloral hydrate one ton a day is consumed in England and America. He then spoke of the causes of this increase. A large portion of the death-rate among children was attributed to the abuse by the parents of medicines acting on the nerves. The injurious effects of patent medicines were considered. In conclusion, he recommended:

1. The examination of all proprietary medicines by a Government or State Commission of experts, who shall have the power to permit the sale of such as are harmless or especially likely to prove serviceable, and to prohibit the sale of all which are peculiarly liable to do injury, and those which are found to be worthless and frauds upon the public. Such a commission was appointed by the Japanese Government several years ago, and has been found to be of great service in that country.

2. The instruction of the public to properly estimate drugs, and to regard every unknown medical agent as dangerous and endowed with capacity for harm. Let them escape the caustic criticism of Molière upon those who pour medicine about which they know little into bodies about which they know less, in order to cure disease about which they know nothing at all.

Dr. Henry Hartshorne, of Philadelphia, read a paper on

CONTINUOUS PREVENTIVE DISINFECTION OF HOUSE-DRAINAGE.

He first referred to the experience in an epidemic of diphtheria and scarlet fever, in which large quantities of sulphate of iron and burning sulphur were used in the sewers. Following this there was an almost absolute cessation of the disease. It may be that, although such substances do not destroy the bacteria, they may neutralize the products of bacteria, which by many are supposed to be the cause of the results which are seen.

We need to destroy all filth in which these germs multiply, and to neutralize the products of their growth. This should not be done spasmodically but continuously. Recently an apparatus has been introduced by which this may be accomplished. It is connected with the bowl of the water-closet, and supplies a strong solution of chloride of zinc at the rate of twenty drops per minute. This prevents all decomposition. The chloride of zinc has no effect upon lead and iron. The speaker thought that if this system could be introduced throughout the city of Philadelphia epidemic diseases would almost entirely disappear.

The following papers were also read at the morning session: "The Relations which the Topography of Harrisburg, Pa., bear to its Drainage and Sewerage," by Dr. Hugh Hamilton, of Harrisburg; "Healthy Dwellings," by Dr. V. C. Vaughan, of Ann Arbor, Mich.; "The Majesty of the Law of Sanitation," by Rev. J. Andrews, of Chestnut Hill, Pa.; "Elevation of the Standard of Supplies," by Mr. H. Wharton Amerling, of Philadelphia.

Adjourned.

Afternoon Session.

Dr. C. W. Chancellor, of Baltimore, read a paper on

HEREDITY AND OTHER PECULIARITIES AFFECTING HEALTH AND LONGEVITY.

This was followed by a paper by Dr. H. C. Wood, of Philadelphia, entitled

HYGIENE OF OLD AGE.

Leaving out of consideration deaths from accidents, fevers, lightning-strokes, and other more or less preventable causes, the man who is so built that he is equally strong in all his parts lives out his appointed days. Excessive strength in one part is a veritable source of danger. The athlete perishes because his over-developed muscular system perpetually strains and finally wears out the heart or lung, which was originally constructed for a muscular apparatus of half the power of that which is artificially built up. The large proportion of mankind die early on account of some local weakness. Human age is not to be accounted by years. In some individuals the general tissues are older at fifty than in others at one hundred. Many of the cases of so-called neurasthenia and nerve exhaustion in men and women, with sudden or gradual breakdown at forty or fifty, apparently from overwork, are really cases of premature old age, and they are to be treated in precisely the same manner. A large proportion of early deaths are the result of some feeble organ being originally endowed with a longevity less than the rest of the organism.

The man who enjoys fair health at seventy-five has probably been built upon the principle of the famous "One-horse Shay," described by our inimitable Holmes, and he should be treated as a wise man would treat such a venerable instrument of progression. The principle involved in such cases is that of protection, and especially protection from strain of any feeble part. Exposure to inclement weather, especially to high winds, is injurious, by throwing a great strain upon the heart, and this may result in sudden death, or, if it does not, may lead to a fatal pneumonia. Emotional disturbance, as the sudden receipt of good news, may have a like result. Medicines that perturbate and measures that bring relief by inducing a violent local action are to be avoided; at the same time incipient disorders should, if possible, be arrested at once.

In regard to details, every old person should go over, with a wise counsellor, his whole method of living and personal habits. The first question is in regard to food. The lost teeth should be replaced by artificial ones to facilitate chewing; but even then the food should be soft, easily comminuted, and readily digested The food should not be of a stimulating character. Many old people are injured by too much nitrogenous food. Milk and breadstuffs cooked with milk should form a large part of the diet of the aged individual. Excessive quantities of food should be avoided. Many old people are more comfortable, enjoy better health, and probably live longer for the use of wine. The habitual use of wine in youth or in middle age, in vigorous health is, I think, a harm rather than a good. But when the powers of life are failing, when digestion is weak, and the whole system feeble, one or two glasses of generous wine at dinner aids digestion, and quiets for the time being nervous irritation. The danger of the formation of any evil habits when a man is past seventy is very slight, and no conscientious physician need hesitate in recommending the daily use of alcoholic beverages to his patient.

In many cases of death the final result is due to cold and the failure on the part of the body to keep itself warm. In the old, the heat-making functions are exceedingly low, and few old people are comfortable in a room the temperature of which is lower than 80°, and abundance of warm but light clothing should be provided. There is no ordinary garment which compares in heat-preserving power with the buckskin jacket, and every man beyond the age of seventy should provide himself with such a garment. At first it should be worn only out of doors, but later, it should form part of the habitual underclothing. If worn as an under-jacket, it should be perforated; when there is a tendency to abdominal weakness or to pendulous abdominal walls, a flannel bandage should be worn. The mechanical effects of an abdominal bandage in affording support to the abdominal organs and vessels are well known.

Dr. Laurence Turnbull, of Philadelphia, in discussing the paper, referred to some of the causes of death in the aged. Too much exercise was one of these. When an old person walking up an elevation, or against the wind, feels an oppression in his chest or a pain in his back, he should stop. Exposure to night air is bad for the aged, and often leads to bronchial catarrh and pneumonia; a night-cap should be worn in bed. Flannel underwear should also be worn; exposure to the sun should be avoided in summer.

He agreed with the author of the paper in all points, with the exception of his recommendation of wine. If a stimulant is required at all, it should consist of alcohol and water in a definite mixture, rather than of wine, and withdrawn when the patient is able to take a sufficient quantity of stimulating food. Old age is no protection to the temptations incident to our physical natures; rather does it weaken the resistance to these temptations, and more than one medical man can recall painful instances where a youth of probity and a middle age of honor has been darkened by an intemperate old age. Mr. Wickfield, in "David Copperfield," is by no means an unreal character in life.

Dr. Russel Thayer read a paper considering the relative advantages of "Forced Ventilation and Ventilation by Heat."

Colonel George E. Waring, Jr., of Newport, R. I., made some remarks on the "Drainage and Sewerage of Cities and Towns."

Dr. Charles K. Mills read a paper on

THE INFLUENCE OF OVERWORK IN THE PRODUCTION OF NERVOUS DISEASES AND INSANITY.

The forms of insanity which are more particularly attributable to overwork are paretic dementia, primary dementia, and confusional insanity. Numerous examples of breaking down and insanity following exciting and prolonged political contests were given.

Dr. P. D. Keyser, of Philadelphia, considered the subject of "Defective Vision in School Children."

Dr. William M. Welch, of Philadelphia, read a paper on

VACCINATION.

He considered bovine and freshly humanized virus of about equal value, while the former was not open to objections which had been made to the latter. Long humanized virus had a slower incubation and ran a more rapid course, although the durability of the protection is probably not so great; but the short incubation recommends the long humanized virus for use where vaccination was performed after exposure to small-pox.

Evening Session.

Dr. Charles Smart, Major and Surgeon, U.S.A., read an address on

WATER-SUPPLIES OF TOWNS AND CITIES.

Friday, May 14th.—Third Day.

Dr. John M. Keating, of Philadelphia, read a paper on

ARTIFICIAL FEEDING.

Examination of the census reports shows that the greatest number of deaths among infants occurs during the first year of life. The dreaded second summer does not exist. This fact suggests the necessity for an improvement in the diet of infants.

If mother's milk cannot be procured, cow's milk, properly prepared, is the next best. The proportion of casein must be diminished, while the proportion of sugar and cream and bone-forming matters must be increased.

As next in value the use of condensed milk was recommended, in the proportion of one part of milk to ten of water. To each half-pint of this mixture one ounce of cream should be added.

The following papers were also read: "The Water-supply of Philadelphia," by Dr. J. Cheston Morris, of Philadelphia; "Disposal of Human Excreta by Fire," by Dr. W. S. Ross, of Madisonville, Ky. (the speaker presented the model of an apparatus which he had devised for this purpose); "The Financial Aspect of Sanitation," by Dr. Alfred L. Carroll, of West New Brighton, N. Y.; "The Sanitary Significance of Sporadic Typhoid Fever," by Dr. Pemberton Dudley, of Philadelphia.

Dr. W. L. Zuill, of Philadelphia, then read a paper on

THE CARE OF ANIMALS IN THE PROPAGATION OF VACCINE.

He described in detail the method of caring for and operating on animals. The selection of the animal is a matter that requires careful consideration. He considered the ivory points, which should be double charged, as the best means of preserving the virus.

He had experimented with glycerine as a preservative for vaccine virus. The lymph is carefully collected, and to it is added an equal weight of glycerine. The mixture is then filtered. It has been found that this preserves its powers for *months*.

Dr. W. F. Hyer, being called upon, made some remarks with reference to the Mississippi State Board of Health.

The Convention then adjourned.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN SURGERY.

Stated Meeting, May 10, 1886.

Stephen Smith, M.D., Chairman.

THE RESULT OF OPERATIONS IN FORTY-ONE CASES OF ABDOMINAL SURGERY AT BELLEVUE HOSPITAL.

The Chairman remarked that some time since he read a paper before the Academy "On the Results of Operations in Bellevue Hospital at the Present Time Compared with the Pre-antiseptic Period." He did not verify his statement with statistics, as he at first intended to do, and could have done but for want of time. He had received many letters from physicians in different parts of the country, as had also the editor of The Record, inquiring if facts would sustain the statements made in the paper. The paper of Dr. Polk is an answer to those inquiries so far as relates to one branch of surgery at Bellevue. It should, indeed, be regarded as a sufficient answer to every doubt which anyone entertained as to the accuracy of the entire paper. For it may be truthfully said, that wherever abdominal and pelvic surgery can be successfully practised, other branches of surgery ought to be even more successfully practised by the same methods. Aside from the intrinsic interest, therefore, which attaches to the subject of the paper about to be read, it will prove doubly interesting by its complete vindication of the antiseptic process so carefully followed in perhaps the most unfavorable atmosphere in the city.

Dr. W. M. Polk said his paper was based upon the cases of peritoneal surgery which had occurred in Ward 23 of Bellevue Hospital during the last three years, more than one-half of the operations having been performed during the last twelve months. They represented all the abdominal surgery done in that ward since he had had charge of it, and about one-third of all done in Bellevue during that time. All the operations reported had been done by himself excepting two, which were performed by Professor Lawson Tait at Dr. Polk's request.

The author then read the histories of only such cases as appeared to offer special items of interest. The first was a double tumor of the uterus, one a fibro-cyst being as large as a child's head and requiring much time for its removal on account of close adhesions. The patient, however, made a good recovery.

The second was one of Tait's operation, and owing to constant efforts at vomiting the intestines were much exposed; carbolic-acid solution was employed as was usual at that date, February, 1883. An abcess developed at the site of the incision, and the patient died of general peritonitis. Dr. Polk thought that but for the defective execution of the operation, recovery would have taken place.

The third case was one of single cystic colloid tumor, with thick fluid, containing papilliform growths, in a woman aged sixty-seven, who died six days after the operation of purulent exhaustion. The age of the patient and the nature of the tumor were the unfavorable features in the case.

The fourth case was one of fibroid tumor of the uterus, which caused excessive pain. The patient was addicted to alcohol, and her condition was poor, but she recovered after a sharp attack of peritonitis.

The fifth was a large fibroma of the left ovary and a cystic tumor of the right ovary the size of the fœtal head. Both tumors were removed, and the patient made an excellent recovery.

The sixth was a fibroid tumor of the uterus, removed by abdominal section, the patient recovering without any untoward symptoms.

The seventh was one of pyo-salpinx with cystic ovaries; the patient had had a number of attacks of peritonitis, each apparently threatening her life. The tubes and

ovaries were quite adherent; the patient had rather a sharp attack of local peritonitis after the operation, but recovered.

The eighth case was a subperitoneal hematocele filling the entire pelvis. Owing to the prominence of the tumor, Dr. Polk made abdominal section with the hope of stitching the sac to the abdominal incision, but after emptying it and washing out with bichloride solution, 1 to 5,000, the sac had so shrunken that it was impossible to do this, consequently a drainage-tube was introduced down through the abdomen. The patient made an excellent recovery.

The ninth case illustrated what could be done in the way of extirpating the tubes and ovaries where there were very firm and extensive adhesions. The patient had two cystic ovaries and a hydro-salpinx upon the right side. She recovered from the operation without an untoward symptom.

The tenth was a case of chronic inflammation of the fallopian tubes, with adherent ovaries, and the uterus bound down posteriorly in the pelvis. He made the usual section, and attempted to ligate the tube on the left side, but the ligature cut through. Other ligatures did likewise, and he was compelled to lift the uterus out of the pelvis and ligate the uterine artery and left ovarian vessels, which left the uterus to be nourished by the vessels from the right side. The patient had a sharp attack of peritonitis, but recovered.

The next three cases were cases of vaginal hysterectomy for carcinoma. The first patient, operated upon three years ago, died of sepsis which undoubtedly entered the drainage-tube. In the other cases, instead of using a drainage-tube he stuffed the opening left by the operation with iodoformized gauze, and the patients recovered.

The last case which Dr. Polk reported was one of removal of a spleen from the pelvis. The patient came to his ward about two weeks ago, suffering a great deal of pelvic pain from what he took to be a distended fallopian tube closely adherent to the right side of the uterus. When he opened the abdominal cavity he found extensive adhesions covering the whole roof of the pelvis, involving the sigmoid flexure, the vermiform appendix being drawn toward the centre of the pelvic brim. A kidney-shaped mass lay in the pelvis, its curve corresponding closely with the curve of the pelvis, resting between the bladder and uterus, its lower point being in contact with the anterior face of the uterus, the uterus being crowded down and backward into the hollow of the sacrum. The mass was enveloped in peritoneal tissue. At first Dr. Polk thought it was a displaced kidney, but on enlarging his incision and feeling for the kidneys, these organs were found to be in their normal position. He then removed the mass, which Dr. T. Mitchell Prudden had since examined and found to be the spleen in a condition of chronic interstitial splenitis and peri-splenitis. The operation was performed five days ago, and the patient was doing well.

Dr. Polk said further that eight of the forty-one operations were performed in the amphitheatre of Bellevue Hospital, before the class of the University Medical College, and all made an excellent recovery. Three or four were done in the general body of the hospital, and they also did well. The remainder were done in a private room in the pavilions. Cases of diphtheria and other contagious diseases were sometimes brought into one of the pavilions in which a part of the operations were performed, but before doing the operation the rooms were thoroughly fumigated. These patients did well.

Of the patients who recovered six had peritonitis; but three had it to a degree to cause uneasiness. Union by first intention was secured in all the abdominal wounds but five; in four of these a small amount of pus formed along the sutures. In one primary union of the peritoneum was obtained, but most of the remainder of the cut surface healed by granulation. Twenty-two were cases of Tait's operation; twenty-one recovered, one died. The one died, the author thought, as the result of a faulty operation, and not as a result of the surroundings. Hegar's operation of oöphorectomy for a fibroid was done in two cases, both of which recovered. There were eight ovariotomies, seven of the patients recovering. Abdominal hysterectomy for fibroma was performed twice, both patients recovering; partial ablation of the uterus for a fibro-cyst in one case, with recovery. Vaginal hysterectomy for carcinoma three cases, with two recoveries. Subperitoneal hematocele two cases, and one death. Abdominal hernia one case, with recovery. The last operation was the one performed on Thursday last, and the patient was doing well.

These results, obtained in a general hospital like Bellevue, many of the operations having been performed before a large class, encouraged the author to believe that they could perform abdominal section in Bellevue Hospital with as good results as anywhere else.

Dr. Polk made some remarks with regard to blood coming in contact with the peritoneum, and said that formerly he, as well as other surgeons, regarded this accident with almost as great apprehension as when pus entered the peritoneal cavity. But experience had taught us that probably a great deal more mischief had resulted from the manipulations necessary for the complete removal of blood from the peritoneum than the blood would have caused had it been allowed to remain. At present he followed the example of Mr. Tait, and paid no attention to the mere oozing of blood after the detachment of adhesions; for this he simply put in a drainage-tube during some hours after the operation to guard against the blood rising in the peritoneal cavity.

Dr. Paul F. Mundé said the author was to be congratulated upon the remarkably good results which he had obtained in peritoneal surgery in Bellevue Hospitall It had been said some years ago that Bellevue Hospita. was a sort of pesthole, and the first successful ovariotomy performed there excited wonder. The results obtained by Dr. Polk and his colleagues showed plainly that such an alleged evil condition of things did not obtain at that hospital to-day. Unquestionably attention to antiseptic methods and absolute cleanliness, and also increased experince in abdominal surgery, explained why present results were so good. There was no reason, in his opinion, why Bellevue Hospital should not be as good a place to do laparotomy as any other place in the world, unless it were in a private hospital, or at the house of the patient, where there was freedom from all septic influences. He could not avoid the conviction, however, that there were times when public-hospital operations did not do so well, notwithstanding the precautions which might be taken to prevent septic infection. He had performed laparotomy thirty-one or thirty-two times at Mount Sinai Hospital, some of the cases being of the most serious nature, yet the patients recovered against his expectations. In some of the cases, however, the operation was comparatively simple, and was performed in a private room, yet the patients died of septicæmia. So far as was known, all possible precautions had been taken to prevent sepsis. While the results of peritoneal surgery had been comparatively good at Mount Sinai Hospital, the percentage of successes had not been quite so great as that obtained by Dr. Polk, notwithstanding the fact that the hospital was not so large a one as was Bellevue.

Dr. H. Griswold had performed abdominal section in four cases in private practice, in some the operation being done in tenement houses; three of the patients recovered, one died after some days of exhaustion.

Dr. Hoit, of Canandaigua, had been much interested in the paper. The excellent results obtained by Dr. Polk in gynecological operations at Bellevue Hospital recalled a paper read recently by Dr. Vander Veer, in which that surgeon gave the results of thirteen operations in the Albany hospital. The percentage of success was about the same, but Bellevue Hospital was a larger hos-

pital. Dr. Hoit thought the advantages afforded by a hospital in the way of increased assistance, instruments, etc., would more than compensate for the disadvantages of congregating patients in large numbers.

The Chairman asked Dr. Polk how the spleen in his last case came to be in the pelvis.

Dr. Polk said the history of the case threw no light on that subject. Dr. Prudden had told him that he had never seen a similar case.

Dr. H. J. Boldt had seen in German literature within a year the report of a case of displacement of the spleen below the umbilicus.

Dr. Mundé could not recall a similar case; he had one of displacement of the *enlarged* spleen downward.

Dr. Polk, in speaking of the details of his operations, said he never used the spray, but he used plenty of soap and water and a solution of bichloride of mercury, 1 to 2,000 or to 5,000. The instruments were all cleansed by one nurse, who was made responsible for them. The sponges were cleansed at his home, and were carried to the hospital by himself; he also cared for the sutures. No person besides himself was allowed to touch the sponges or sutures except the house-surgeon; no hands entered the abdominal cavity except those of the operator and house-surgeon, and Dr. Polk made himself responsible for the cleanliness of the house-surgeon's hands as well as of his own. The wound was subsequently covered with iodoformized gauze. This personal attention to details he thought accounted for the successful results which he had been able to report this evening.

On motion of Dr. De Garmo the author was requested to read his paper at a future meeting of the Academy.

Correspondence.

THE DISINFECTION OF RAGS AND "DR. SMITH'S" PETITION.

To the Editor of The Medical Record.

Sir: In view of the strictures recently published in the medical journals upon the course of numerous reputable physicians who have signed a paper declaring that disinfection of rags from foreign ports is a proper sanitary measure at present, a few words may be permitted by way of explanation and correction. In the first place, all who have read the paper in question will corroborate the statement that it in no way favors any *particular* plan for disinfection. The entire sum and substance of it all is that in view of the fact that cholera has thus early appeared in various places on the Mediterranean coast, this city is in greater danger of a visitation of the disease than it has been heretofore, and that no measures which can possibly be employed to prevent its introduction should be neglected.

Is there any "good-natured" physician, or otherwise, who would feel justified in refusing his indorsement of such a statement in view of all the facts as they exist to-day.

The safety of this community lies in the vigilance of the Health Officer of the Port, who is Dr. Smith. Is it desirable that he should continue to exercise the discretion vested in him by law according to his *own* judgment, or in accordance with the wishes of an interested faction of business men who have no responsibility to the public in this matter?

Grant, if you please, that Dr. Smith has recommended a process of disinfection which increases the cost of imported rags five dollars per ton. This is just a quarter of a cent per pound, and if importers find that tax too high and will cease importation entirely for the present, I believe the lives of our citizens would be far safer. London still prohibits the importation of all rags from Spain, and every medical or business man of New York will be clamoring for the same course here after the disease has once been allowed to slip through the quarantine establishment.

I am in no sense desirous of defending my own action in signing the petition, as I am convinced that the gravity of the situation justifies my course and that of all who have signed it. But there is danger that public sentiment, which is very often wrong, will be lulled into a state of mistaken security by the criticisms of Dr. Smith, and realize their error when it is too late to apply an efficient remedy. Very respectfully,

Daniel Lewis, M.D.

[There is no doubt that Dr. Lewis and the other gentlemen who signed the document did so in good faith, but still there was no guarantee against its use for the purpose of booming the present method of rag disinfection, which is perfectly worthless.—Ed.]

SNAKE VIRUS AND HYDROPHOBIA.

To the Editor of The Medical Record.

Sir: The claims of the physician in Spain who has lately announced his *discovery* that inoculation with the virus of certain snakes is a preservative against hydrophobia in men and animals brings to mind the venerable saying, in another dress, "Il n'y a de nouveau que ce qui est oublié." The physician in question claims to have made a vast number of observations on dogs that have been bitten by vipers, and has found that they are incompetent to take the disease when afterward bitten by hydrophobic dogs. He claims that his experiments have proved entirely successful. I do not know whether the announcement of this curious treatment is likely to be taken advantage of by our lay journals to revive the hydrophobia scare, or that it is a matter which is likely to give the medical fraternity much concern; but it may be of some interest, from a historical point of view, to refer to the fact that in the *Journal d'Economie Rurale*, 1805, will be found the announcement of the method of M. Gauchi, Mayor of Reorthe, for preserving animals, and particularly dogs, from hydrophobia, which consisted in having them bitten by a viper previously bitten by the animal which was rabid; because, as he reasoned, the poison of the viper does not neutralize the poison of the hydrophobia if applied after the bite of the dog. His experience had taught him that dogs which had been bitten by rabid animals did not become rabid if previously bitten by a viper and a swelling had been produced.

Yours faithfully,

Joseph A. Andrews, M.D.

May 21, 1886.

THE VALUE OF MUSCULAR EXERCISE IN TREATMENT OF DIABETES MELLITUS.

To the Editor of The Medical Record.

In the discussion on the subject of the treatment of diabetes which occurred in the New York Academy of Medicine, on March 18, 1886, I took occasion to emphasize the importance of active and passive exercise adapted to the requirements of each case. I remarked, that so convinced was I of the value of this therapeutical measure, that I had adopted the method of compensating my diabetic patients for taking the prescribed exercise by a definite allowance of white bread (for which they all crave), graded according to the amount of exercise taken.

This treatment, based upon the well-known recommendation (empirical at that time) of Bouchardat, has suffered unmerited neglect, if we are to judge from the absence of any allusion to it in the discussion referred to. Indeed, one of the speakers, whose clinical experience is large, and whose opinions are justly esteemed, expressed the regret that, aside from the dietetic treatment, there is nothing but empiricism in the therapeutics of diabetes. In reply to this asseveration I felt called

upon to say that the recognition of muscular exercise is an important element in the treatment of this malady as the logical outcome of well-established physiological facts, and therefore its application is strictly scientific.

Physiology teaches that the liver and muscles are the most active agents in absorbing sugar from the blood and converting it into glycogen, which in its turn is utilized for the maintenance of the body.

In diabetes the glycogenic function of the liver is either in abeyance or greatly impaired, while the muscles also fail in a great measure to perform their function of disposing of sugar. We resort to the restriction of the sugar supply by diminishing or withdrawing those articles of diet which physiology has taught are sugar-producing. We possess no remedy which increases the glycogenic function of the liver, but we are in a more favorable position regarding the muscles. By increasing their functional activity we can stimulate the sugar-converting function of the interfibrillar substance of the muscles, and then we may dispose of a large portion of the excess of sugar circulating in the blood.

Clinical experience is fortunately entirely in accord with this deduction from the teachings of physiology. This fact has again and again been exemplified. It is nothing new; but its true import is unfortunately but too often lost sight of in the eager search for anti-diabetic, dietetic, or medicinal specifics. The subject of exercise is often dismissed by directing the patient to exercise in the open air without fatiguing himself. The insufficiency of this injunction is within the experience of every practical physician. It is a well-known fact that diabetics are, as a rule, loath to muscular exertion; lassitude is a common symptom, and something more than the mere suggestion is required to enforce the necessity of exercise upon these patients. Being based upon strictly scientific data, *the prescription of exercise should be as precise and exacting as that of the diet*, if we would obtain the legitimate advantages.

Dr. William Richardson, in his book on diabetes, furnishes us with a personal experience which all practical physicians will at once appreciate. He describes graphically how he was himself overcome by weakness and indisposition to exertion when suffering from diabetes.

"He could not walk a hundred yards without great fatigue; he frequently fell." "I began to take exercise regularly two or three times a day; wet or fine, I took it." "Gradually I gained strength, so as to be able to walk five or six miles a day without fatigue." "The exercise should be regularly sustained day by day; even in wet weather it should not be intermitted; of course great care should be taken against wet feet; it should never be carried to real fatigue; a feeling that exercise has been taken is the most that should be felt. To carry into effect regular and sustained muscular exercise requires great moral courage and energy, the languor and feeling of weakness are so great; but if the exercise be only carried out patiently and perseveringly the task will become not only more and more easy, will soon no longer be a task, but positively a pleasure."

I take occasion to again call attention to this point, because its importance, which I endeavored to emphasize in the description at the Academy, has since that time been again brought forward in the discussion of the same subject by the Fifth German Congress for Internal Medicine (THE MEDICAL RECORD, May 15, 1886, p. 573). Professor Stokvis, of Amsterdam, said: "He insists on muscular exercise, by *which alone* the percentage of sugar can be greatly diminished."

Professor Hartman said: "Alkaline remedies, the opiates, *active muscular exercise*, or muscular massage where the patient is not able to take active exercise, and observance of a good hygienic *régime* in general are the means he relies upon."

Professor von Mehring "had invariably noticed *considerable decrease, and even disappearance*, of sugar from the urine after prolonged active and passive exercise."

Professor Finkler "has the records of thirteen cases of diabetes, in which he succeeded in reducing the sugar in the urine from four hundred grains to one hundred and fifty grains and less per day by active and passive exercise, allowing small quantities of hydrocarbons. In some cases the sugar disappeared entirely."

In the discussion of the subject in the New York Academy of Medicine, referred to above, the writer's earnest advocacy of muscular exercise in diabetes was met by the argument from the principal speaker that it is very dangerous to make those suffering from the severe forms of diabetes take much exercise, although in ordinary cases exercise in the open air within the limit of fatigue is important and necessary; and another gentleman expressed himself wholly in accord with this view, as he had seen coma in children develop shortly after admission to the hospital, due to the fatigue and excitement, and in London it had been observed after long railway journeys.

Fearing lest these opinions may deter many from resorting to a measure which is so full of promise to the diabetic, I desire to reiterate what I said on that occasion, viz., that all valuable therapeutic measures are potent for evil as well as for good, and that a judicious selection of cases will eliminate possible dangers. That the latter have been exaggerated would appear from Professor Stokvis' essay, who says that diabetic coma *might* result from sudden and abundant production of acetone, etc., coming on *after unusual exertion—the fatigue of a long journey*.

Again, by a singular coincidence which demonstrates the great value of THE RECORD to the practical physician, the same number gives us in the able essay of Dr. Devlin important evidence on this point. On p. 545 Dr. Devlin reviews the histories of many cases of diabetic coma by Foster, Schmitz, Frerichs, Jaenicke, Jaksch, Quincke, and others. He says: "Among the important lessons drawn from these the most obvious is, that in them *the history of previous fatigue or over-exertion rarely appears*" (p. 549).

Without entering fully into this subject, which I propose to elaborate at some future time, I would ask a careful consideration of the clinical facts which I have here hastily brought together in addition to my personal experience.

SIMON BARUCH, M.D.

43 EAST FIFTY-NINTH STREET.

A SIMPLE METHOD OF KEEPING THE HYPODERMIC SYRINGE IN ORDER.—Dr. D. Tod Gilliam, of Columbus, O., writes: "A simple and efficient method for keeping the hypodermic syringe in order is as follows: Draw out the piston-rod, immerse the syringe in water, then push the piston home, when the chamber of the syringe back of the piston-head will be found filled with water which entered at the orifice through which the rod plays. This will not leak out, will keep your syringe in prime order, ready for any emergency, and will save money as well as annoyance by enabling you to use a syringe that would otherwise be discarded. As the device is so simple, entails no trouble, and the syringe being once filled need not be looked after for weeks or months if need be, I I thought it worth mentioning."

SPLENECTOMY GROWING IN FAVOR.—At the last meeting of the Medical and Chirurgical Society, London, Mr. Knowsley Thornton read a paper in which he related the particulars of two cases in which he had performed splenectomy. One ended fatally from internal hemorrhage following the operation. In the other, complete recovery ensued, but the girl acquired an enormous appetite. It had been noted in animals that the running powers and appetite were increased after the performance of experimental splenectomy.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 16 to May 22, 1886.

ELBREY, F. W., Captain and Assistant Surgeon. Sick leave of absence still further extended one year on surgeon's certificate of disability. S. O. 115, A. G. O., May 17, 1886.

CASTER, WILLIAM F., Captain and Assistant Surgeon. Granted leave of absence for one month, to take effect about June 1st, with permission to apply for an extension of one month. S. O. 55, Department of Texas, May 11, 1886.

BANISTER, JOHN M., Captain and Assistant Surgeon. Assigned to duty as Post Surgeon, Fort Canby, W. T. S. O. 75, Department of Colorado. May 8, 1886.

EWING, C. B., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Leavenworth, Kan., and ordered for duty as Post Surgeon, Fort Supply, Ind. T. S. O. 48, Department of Missouri, May 13, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 27, 1886.

LAW, H. L., Surgeon. Ordered to the U. S. R. S. Wabash.

HAWKE, J. A., Surgeon. Detached from U. S. R. S. Wabash, and wait orders to sea.

OGDEN, F. N., Assistant Surgeon. Detached from U. S. S. New Hampshire, and wait orders.

BAKER, J. W., Assistant Surgeon. Ordered for examination preliminary to promotion.

WOODRUFF, CHARLES E. Commissioned Assistant Surgeon in the Navy, May 17th.

HENRY, CHARLES P. Commissioned Assistant Surgeon in the Navy, May 18th.

A PLEA FOR RATIONAL THERAPEUTICS.—Under this title Dr. S. C. Dumm writes in the *Columbus Medical Journal* against agnosticism in therapeutics. He thinks that, while some diseases may eventually disappear if left to take their own course, almost all can be shortened or favorably modified by appropriate medication. Much permanent injury might be avoided by timely treatment, he asserts, which it would be criminal to withhold. The point made by the writer is enforced by the citation of several illustrative cases. There is little doubt that as much harm is done by a neglect of suitable remedies as by over-drugging. In medicine, as in everything else, there is a happy mean, to preserve which is the secret of success.

DR. HUTTON, OF FERGUS FALLS, MINN., ON DIPHTHERIA.—Dr. T. J. Hutton sends us some interesting facts concerning "Specific Treatment for the First Stage of Diphtheria." His opinions have been published previously in THE RECORD. He has treated, during the past five years, nearly two hundred cases of the disease. He regards diphtheria as a specific, septic sore throat; the typical form, unmodified by treatment, has three stages, viz.: First, a septic sore throat; second, laryngeal stenosis or sepsis; third, death from suffocation or sepsis. It is caused in man and beast by "crowd-poison," and the majority of attacks originate *de novo*. A sore throat from any cause makes diphtheria more easily contracted. The poison, once conveyed there, may develop deadly outbreaks in the cleanest and best-ventilated houses. The ultimate cause of diphtheria is waste body-matter eliminated in the breath. This body-waste or crowd-poison may return to the throat in gaseous form. In the region where Dr. Hutton practises the air is very pure, and the hygienic surroundings exceptionally good. He claims that his plan of treatment is specific—"not specially favorable, a sense in which this word is sometimes used, but infallible." The only limitations are that the disease shall be uncomplicated, and that the patient shall have been previously healthy He claims to have controlled diphtheria, grafted on tonsillitis, in markedly scrofulous subjects. His plan of treatment is essentially as follows: Fresh air is to be obtained under all circumstances. If the weather is not too cold, he keeps patients out of doors. He has the body, especially the extremities, kept comfortably warm, and enjoins perfect quiet in the sick-room. In later stages hot-water bottles may be placed around the patient if necessary. At the very outset a careful and deliberate examination is made of the throat, and the pseudo-membranous spots are painted with a solution of nitrate of silver, containing twenty to forty grains to the drachm of water, applied on a small camel's-hair pencil. The painting operation is proceeded with slowly, care being taken that every affected spot is completely touched up. If gagging occur, it is well; it throws every chink and cranny of the throat into full view. The strength of the solution depends on the age of the patient, the severity of the case, and the condition at the time of the first visit. The number of applications may vary from one to thirty. The applications, if properly made, are painless, as they are made to necrotic tissue void of all feeling. It may be well to remember that applications made accidentally to sound parts give to such parts the appearance of pseudo-membrane. All patients old enough to do so are required to gargle with a saturated solution of chlorate of potash until the symptoms ameliorate. Where gargling is impossible, *e.g.*, with young children, the remedy is given internally. Where a case has already advanced to a stage of severity, iron and quinine are added to the potash. A laxative (preferably calomel and soda) is given at the outset. Concentrated nourishment and stimulants, if necessary, are essential. As a disinfectant, particularly in nasal cases, carbolic acid is used.

MALARIA AND SMALL-POX.—During an epidemic of small-pox in a town in Italy Dr. D'Ortensio observed that the course of the variola was modified by an intercurrent attack of malarial fever. A patient upon whom the variolous papules were well developed was seized with a typical malarial paroxysm. The eruption almost immediately disappeared, but upon the cure of the fever by quinine the papules again made their appearance, and the small-pox ran its regular course.

AID FOR PASTEUR.—The French Government has been asked by Pasteur for a subsidy of 2,000,000 francs for the establishment of a hospital, and for 50,000 francs a year to operate it. It is said that the authorities are in favor of giving him at least the latter grant. The Académie de Médecine has already voted a grant of 10,000 francs to his institute.

THE "SPOOL OF THE BREAST."—Dr. H. V. Hull writes, in the *Albany Medical Annals*, that he was consulted by an Irishwoman, who told him that her daughter was not well, and that she thought "the spool of the breast was fast to the spine." She explained that a girl in the old country had had similar symptoms, and was relieved by the application of a cupping-glass over the lower end of the breast-bone, by which process "the spool was loosened." The girl seen by Dr. Hull was suffering from indigestion. The writer subsequently learned from a friend versed in Gaelic that the word "speal" meant "sword," and therefore the "speal of the breast" meant the "sword of the breast," or the xyphoid cartilage.

THE USE OF ATROPINE FOR PURPOSES OF DIAGNOSIS.—Dr. Barraquer writes, in the *Boletin de la Clinica Oftalmologica*, in condemnation of the practice of employing atropine to dilate the pupil prior to examination with the ophthalmoscope, as he says much damage may be caused by its indiscriminate use.

THE TREATMENT OF ANEURISMS BY THE INTRODUCTION OF WIRE.—The comparative powerlessness of modern surgery to effect a permanent cure of considerable aneurisms as they occur within the body was markedly shown, says *The Medical Press*, at the last meeting of the Royal Medico-Chirurgical Society, when Dr. Cayley read a communication descriptive of a case of thoracic aneurism treated by the introduction of steel wire into the sac. The patient was a man, aged forty-eight, who entered the Middlesex Hospital June 5, 1885, a pulsating tumor having appeared in his neck five days previously, symptoms of thoracic aneurism having been present since November, 1884. Tufnell's treatment and large doses of potassium iodide were tried without result, and on June 24th Mr. Hulke introduced into the tumor, through a fine canula, forty feet of steel wire. Subsequently a second introduction of wire, thirty-four feet nine inches long, was performed by Mr. Pearce Gould, in an endeavor to arrest urgent symptoms, but death occurred soon after, during a paroxysm of dyspnœa. No constitutional disturbance followed either operation. The discussion which ensued on the conclusion of the paper was both instructive and interesting, and exhibited in marked contrast the different opinions as to the value of operative interference held by physicians and surgeons respectively. Dr. George Johnson's contention, however, that there is danger of local irritation, ulceration, and embolism, associated with the introduction of wire into aneurisms, was not borne out by the history of Dr. Cayley's case, although an instance was cited by Dr. Paul, from the records of the Madras Hospital, in which signs of inflammation were produced by the introduction of horse-hair. Mr. Barwell made a solid contribution to the discussion in the shape of a list of eight cases in which the mode of treatment in question had been adopted, all terminating fatally; but he contended that as yet the value of the proceeding could not be fully estimated. The most cheering view of the situation was taken by Messrs. Bryant and Holmes, who both succeeded in extracting crumbs of comfort from the seemingly hopeless accounts of successive failures; and Mr. Hulke, while condemning such methods as electrolysis and administration of ergot, also appeared to look forward with a certain amount of confidence to the future development of the plan of treatment by foreign substances in the aneurismal sac.

HEMORRHAGE FOLLOWING COITUS.—Dr. Lvoff reports in the *Russkaya Meditsina* a case of a newly married woman to whom he was called on account of a profuse hemorrhage occurring shortly after the first coitus. The hymen was ruptured, but this was not the source of the hemorrhage, as the blood was seen flowing in a steady stream from the mouth of the uterus. The writer believed the hemorrhage to have been due to active congestion of the uterus occasioned by the copulative act.

ERYTHEMA NODOSUM.—At a recent meeting of the Clinical Society, London, the somewhat well-known subject of erythema nodosum was brought to the fore by Dr. Stephen Mackenzie. Assisted by other workers, he has been able to collect particulars of no fewer than one hundred and eight cases. From an analysis of these he found that five females were attacked to every male, and that most cases occurred during the second or third decennial period of life, *i.e.*, during the age-period in which rheumatism is of most common occurrence. There were thirty-four cases (thirty-one per cent.) in which symptoms of rheumatism occurred, and twelve cases in which the patient had previously suffered from it. In twenty cases some definite cardiac lesion was made out. Dr. Mackenzie maintained that he was justified in concluding that erythema nodosum is frequently associated with definite rheumatic symptoms, also that heart disease (endocarditis) may arise during an attack of erythema nodosum, both in cases in which arthritis is present and in cases in which there is no affection of the joints, and that these conclusions justified the inference that erythema nodosum is frequently an expression of rheumatism, even when no other definitely rheumatic symptoms are present.

A NOVEL METHOD OF BLEEDING.—In a case of a woman suffering from very evident overloading of the vascular system, but whose friends objected strenuously to venesection, Dr. Coppinger resorted to aspiration of the jugular vein. The patient had been accustomed to receive hypodermic injections, and made no objection to the introduction of the needle of the aspirator. A sufficient quantity of blood was abstracted in this way, and the patient's urgent symptoms were relieved.

REGULAR POLYGLOTS.—Our esteemed contemporary, *The St. Louis Medical and Surgical Journal*, says that its editors read and translate, with fluency and correctness, French, German, Italian, Spanish, Norse (*sic*), Dutch, and Russian. Happy editors! We can but admire while we envy them. Norse was such a nice language.

QUINSY AS A RHEUMATISM.—At a recent meeting of the Chicago Medical Society, Dr. J. S. Knox read a paper in which he maintained that, in a large proportion of cases, quinsy is a rheumatic inflammation (*Medical and Surgical Reporter*). He was led to this conclusion from having observed the disease, in the vast majority of cases, in individuals of a decided rheumatic tendency; from the success of antirheumatic treatment, and from the similarity between the symptoms of quinsy and those of rheumatism.

THE UTILITY OF OPERATION IN CANCER OF THE BREAST.—Dr. D. Hayes Agnew says that it is very doubtful if, taking the general run of operations for mammary carcinoma, life is materially prolonged.

A RADICAL TREATMENT FOR MASTURBATION.—Dr. J. C. Pennington, of Andover, Mass., writes as follows: "I feel constrained to report a curious case of self-treatment which is worthy of the *Mikado*. The punishment was made to fit the crime in this wise: The patient, a boy of fifteen, being discouraged by his fruitless endeavors to free himself from the worst of all habits, deliberately selected the privy as the theatre of his operations, and, holding the offending organ by the prepuce with one hand, took aim with a small pistol, and shot it, with the other. The ball (22 calibre) entered on the dorsal surface; running beneath the skin it entered the glans behind the corona, emerged on its dorsal surface, and again penetrated the prepuce before making its final exit. At the sight of blood the boy's heroism evaporated, and he screamed for help. As usual the fair sex were most prompt in running to the rescue, and it was some time before a man arrived whom he could take into his confidence. Fortunately the urethra is not wounded, and a speedy recovery may be expected."

CHRONIC STENOSIS OF THE LARYNX TREATED BY A NEW METHOD, WITH REPORT OF A CASE.

By JOSEPH O'DWYER, M.D.,

NEW YORK.

CHRONIC stenosis of the larynx is one of the most unsatisfactory diseases that the physician is called upon to treat. Tracheotomy must be resorted to, sooner or later, to save the patient from a painful death, and, as a rule, in such cases the tracheal tube, with all its attendant discomforts and repulsiveness, has to be worn through life.

Various dilating instruments have been invented for this class of cases, notably by Morel-Mackenzie, Navratil, Whistler, and Schroetter. The metallic plugs or bougies devised by the latter have so far proved the most successful. To use them a tube in the trachea is necessary, but the method is slow, painful, and uncertain. These plugs are made of block tin, somewhat triangular in shape and about one inch and a half in length.

First tracheotomy is performed, then a plug of suitable size is passed through the glottis, and the lower end fastened in the fenestrum of the tracheal canula by means of a bolt, which takes the place of the inner tube. As the stricture is dilated the plug is removed by a string, which is left fastened to it, and a larger one inserted; of these dilators there are twenty-four sizes.

Before devising these short bougies Schroetter tried long vulcanite tubes, which protruded from the mouth and were held in position by the hand. But they could be kept in position only a short time, on account of the severe irritation and constant tendency to retching which they produced. He was therefore compelled to abandon their use.

Bosworth, after describing the different instruments just referred to, and the methods of using them, says:[1] "The treatment of laryngeal stenosis by means of any of the above-mentioned plans is necessarily tedious and protracted, involving, as a rule, a course extending over from twelve to eighteen months. Yet, when we consider the alternatives presented to the sufferer, of submitting, on the one hand, to this tedious process, and, on the other hand, to the terrible prospect of wearing a tracheal tube during life, it would seem that there should be no question as to the advisability of the treatment, provided that it offers any certainty as to the ultimate cure. Unfortunately, this cannot be assured. Schroetter has reported and exhibited a number of cases in which the gradual dilatation by his bougies has resulted apparently in a perfect and permanent cure. On the other hand, it should be stated that others have not usually attained the same uniform success in their efforts."

Although I have treated only a single case of chronic stenosis with my laryngeal tubes, I am fully convinced that they will prove infinitely superior to anything yet devised for the relief of this unfortunate class of sufferers.

In the use of these tubes tracheotomy is never indicated, and ether rarely. They are inserted through the mouth and rest solely in the larynx and trachea, the upper end being completely below the epiglottis. They facilitate rather than interfere with respiration, and permit the patient to swallow solids and semisolids, and, to a certain extent, fluids.

The tubes are two and a half inches long. A cross section presents an elliptical outline, with an antero-posterior diameter about twice that of the transverse. At the upper end of the tube is an expansion or shoulder called the head, which rests in the cavity of the larynx, and serves to prevent its slipping through into the trachea. The head has a posterior curve, to allow the epiglottis to take its normal position and to perform its functions. Immediately below the head is the neck of the tube, which has a very narrow transverse diameter and occupies the chink of the glottis. The rest of the tube, called the body, extends into the trachea, and has the shape of a double wedge to prevent its easy expulsion.

Mrs. Van A——, aged forty, contracted syphilis from a worthless husband twelve years ago, and since then the throat has seldom been free from ulceration. Two years ago the voice became husky, and she began to suffer from shortness of breath on exertion. These symptoms gradually increased, and for two months she was obliged to sleep either sitting in a chair or propped up in bed to almost a sitting position. She came under my care at the New York Foundling Asylum, December 5, 1885. Immediate tracheotomy had been advised a short time previously by one of our leading laryngologists.

She was losing flesh and strength. The voice was husky; and while the patient could breathe fairly well in a state of perfect rest, the least exertion induced severe dyspnœa, accompanied with stridor, and during sleep the respiration was very noisy. Frequent suffocative attacks occurred during sleep, and not only interfered with rest, but kept the patient in constant fear of choking to death. She had pain in the right side of the larynx, and constant soreness and distress in the chest from straining of the respiratory muscles.

Examination of the throat showed adhesion of the soft palate to the posterior wall of the pharynx on both sides. The larynx was examined by Dr. W. K. Simpson, Dr. P. A. Callan, and others. The epiglottis was somewhat thickened and deformed from cicatricial contraction, its posterior surface about the seat of the cushion projecting backward so as to exclude a view of the anterior commissure of the cords. From the base of the right arytenoid there arose a membranous band which encircled the entire left half of the larynx, leaving but a small aperture between the free border of the membrane and the right cord, a small part of the latter only being visible. The left cord was entirely covered. Arytenoids somewhat swollen; no ulceration.

December 5, 1885, at 3.30 P.M., in the presence of Dr. J. L. Smith, Dr. P. A. Callan, and Dr. Dillon Brown, after several trials and the use of much force I passed through the stricture my smallest adult tube, the larynx having been previously sprayed several times with four-per-cent. solution of cocaine. As soon as the immediate effects of the operation subsided the patient expressed herself as breathing better than before the insertion of the tube. She slept the following night, in the recumbent posture, for the first time in over two months, and complained of very little irritation from the tube.

December 6th.—Ate two boiled eggs and a piece of toast for breakfast, which she swallowed without much difficulty, but fluids produced more or less coughing.

December 7th.—Slept well; had some dyspnœa, which

[1] Bosworth, On Diseases of the Throat, p. [illegible]

immediately disappeared when the air was moistened with steam. At 11 P.M. complained of pain in the larynx, and thought she felt the tube change its position. It was therefore removed, having been in the larynx fifty-six hours.

The length of this tube is 2½ inches, transverse diameter of head $\frac{5}{8}$ inch, antero-posterior diameter of neck $\frac{10}{32}$ inch, and transverse diameter of neck $\frac{6}{32}$ inch. In consequence of having to modify the shape of the head of the next tube I was unable to operate again until December 11th. During the interval the patient's breathing was much improved, and she was entirely free from the suffocative attacks during sleep.

December 11th.—At 3.20 P.M. I tried to insert tube No. 2, but it required more force to push it through the stricture than I considered justifiable, and I therefore re-inserted No. 1.

At 2 P.M., December 12th (twenty-two and a half hours later), I removed it, and immediately inserted No. 2 without difficulty.

The antero-posterior diameter of the neck of this tube is $\frac{12}{32}$ inch, transverse diameter $\frac{7}{32}$ inch.

December 13th.—At 2 P.M. the tube was coughed out, twenty-four hours after its insertion. The calibre of this tube was considerably larger than that of No. 1, and allowed free respiration even with moderate exercise.

December 14th.—Tube No. 3 inserted at 7.45 P.M. It has the same dimensions as No. 2 except that the antero-posterior diameter of the neck is $\frac{1}{24}$ inch greater.

December 15th.—Tube caused pain and irritation, with hacking cough, which was relieved by an opiate. It was expelled at 10 A.M., having been retained fourteen and one-fourth hours. For the first time some tenacious mucus was found in the calibre of the tube.

As there was considerable irritation of the larynx it was allowed to rest until December 18th, when No. 3 was reinserted. It was coughed out the next morning, eleven and a half hours after its introduction. As this was the largest tube I had, it was reinserted daily until December 22d. The patient left the hospital December 23d to spend the holidays at home, and returned January 3, 1886. A careful examination of the larynx by Dr. Simpson and others showed no trace of the cicatricial membrane except a narrow band extending between the arytenoids anteriorly. The left cord, which was now distinctly visible, appeared broader than the right and its movements were somewhat restricted. Arytenoids still somewhat swollen; no sign of ulceration; voice good.

As there was ample breathing space in the chink of the glottis and no dyspnœa, further dilatation of the larynx was not considered necessary for the present. She was therefore requested to report for observation once a week and for about six weeks enjoyed excellent health, having gained considerable flesh and strength. But gradually the dyspnœa returned, and she was readmitted to the hospital, March 4, 1886, almost two and a half months from the time she was discharged.

Examination of the larynx showed no material change, there being still ample breathing space between the cords. Therefore the only possible explanation of the return of the dyspnœa was the existence of subglottic stricture, which had recurred. This condition was suspected in the beginning, from the fact that on inserting the tube the lower end after passing the rima was deflected sharply to the left, showing the presence of thickening on the right side, and the force required to overcome the resistance was out of all proportion to what could be offered by the membranous band above the cords. Tubes No. 1, 2, and 3, used on the previous occasion, were passed into the larynx in rapid sucession, and retained from twelve to forty-two hours at a time. On the fifteenth day after admission an additional size, No. 4, was introduced. The antero-posterior diameter of the neck of this tube was one-half inch, transverse diameter one-fourth inch, diameter of head three-fourths of an inch. This tube was worn during the night only until March 31st, when, the stricture being sufficiently dilated, she left the hospital, having been under treatment twenty-seven days.

I now introduce the tube once in two weeks and leave it in over night, and intend soon to increase the interval to a month, which I believe will be often enough to prevent a recurrence of the stricture.

To summarize: During the first period of treatment of eighteen days the tubes were inserted nine times, and retained in the larynx one hundred and seventy-three hours. During her second stay in the hospital of twenty-seven days they were introduced thirteen times, and retained two hundred and four hours.

The introduction and removal of the tubes was accomplished with the same instruments used in intubation of the larynx in children.

I wish to express my obligations to Dr. W. K. Simpson for valuable advice and assistance, and to Dr. Dillon Brown, the resident physician, for unremitting care and attention during the early part of the treatment of this case, which was necessarily attended with more or less anxiety.

Since writing the foregoing a patient was sent to me who has worn a cannula in the trachea for two years for supposed bilateral paralysis of the glottis openers. She was admitted to the New York Foundling Asylum for the purpose of removing the vocal cords, an operation which, as far as I am aware, has never been performed. If incurably paralyzed and lying in apposition these organs are worse than useless, and their removal would not only allow of the free ingress and egress of air, but also the ability to whisper distinctly. It proved to be almost complete occlusion of the larynx from adhesion or growing together of the cords, but whether paralysis preceded this condition or not remains to be seen. Under the influence of ether I enlarged the tracheal opening, broke up the adhesions, and inserted a tube in the larynx, which she is now wearing.

853 Lexington Avenue.

How the Founder of the Society of Friends Set a Dislocated Neck.—In an interesting and scholarly address by Dr. J. J. Levick, on the "Early Physicians of Philadelphia," he tells us how George Fox travelled through New Jersey and New England, keeping a faithful journal of all that occurred. "In 1672 he was passing through New Jersey, then but sparsely settled. He had spent the day with Richard Hartshorne, at Middletown Harbor (the ancestor, if I mistake not, of one of our present Board of Managers, and of three physicians of that name who have so well served this hospital), and next morning went on to Shrewsbury. 'While at Shrewsbury,' writes Fox, 'an accident befell which for the time was a great exercise to us. One John Jay, a Friend of Barbadoes, who came with us from Road Island, being to trie a horse got upon his back, and the horse fell a running and cast him down upon his head, and brake his neck as the people said. They that were near him took him up dead, and carried him a good way and laid him on a tree. I got to him as soon as I could, and feeling on him, concluded he was dead. As I stood by him pitying him and his family, I took hold of his hair, and his head turned anyway it was so limber. Whereupon throwing away my stick and my gloves, I took his head in both my hands, and setting my knees against the tree I raised his head and perceived there was nothing out or broken that way. Then I put one hand under his chin and the other behind his head, and raised his head two or three times with all my strength and brought it in. I soon perceived his neck began to grow stiff again, and then he began to rattle in his throat, and quickly after to breathe. The people were amazed, but I bid them have a good heart and be of good faith; to carry him in the house, give him something warm to drink, and put him to bed. After he had been in the house a while he began to speak, but did not know where he had been. The next day he was pretty well, and many hundreds of miles did he travel with us after this.'"

ON THE ADOPTION OF SOME GENERAL SYSTEM OF DISTRICTING THE NEW YORK STATE ASYLUMS.[1]

By FREDERICK PETERSON, M.D.,

[illegible]

WHEREVER an asylum for the insane is established it will be found that from all directions toward it both the acute and chronic insane of neighboring territory will gravitate. The regions nearest, which find the institution most accessible, are benefited most; and it has been mathematically demonstrated that several times as many insane come from a circle about the asylum having a radius of fifty miles as from the remoter portions one hundred and two hundred miles away.[2]

The people who have insane in charge, the county or city officers who apprehend them, the doctors who examine, the judges who approve the certificates—it is the duty of none of these to determine whether cases are recent or of long standing. They only decide that treatment and custody are required, and see that such cases are removed to the nearest institution for the insane. An asylum becomes, then, the centre of a district to which all the acute and chronic insane of that region will be sent, according to natural laws which no amount of effort can overcome.

Hence, in the older countries such institutions are placed in districts, and in the best attainable positions in such districts. England, France, and Germany are notably so districted. Their asylums receive both acute and chronic insane. The experiment of constructing separately managed institutions for the incurable has been tried abroad and proved undesirable.

Good systems of districting may be found in some of our own States. Pennsylvania is an excellent example, with its five districts and large mixed asylums in their railroad centres. It is contemplated to increase the capacity of each of these to 2,000 beds. This is a rational system. In time these institutions will not be sufficient for all of the insane of that State, and subsidiary districts must be established, while the healthy, quiet, harmless incurables can be given room in county asylums.

The more easily attainable an asylum, the more speedily can cases be put in its charge.

The sooner cases requiring hospital treatment are removed to an institution, the more quickly do they recover.

For the same reason of nearness can the visits of relatives be more frequent when required as a remedial measure, or when prompted by affection for many whom this dread disease may doom to life-long isolation from home and friends.

Though at times it has been found expedient to construct separate institutions for the chronic and acute insane, yet most alienists are agreed, at the present day, that it is not the best policy, and that the hospitals which receive all classes of diseased minds have a wider sphere of usefulness open to them.

The Willard Asylum for Chronic Insane was created by the Legislature at a time when the overcrowding of the insane into poor houses demanded immediate relief, and that it was the wisest action to perform at that time its subsequent history has shown. But the conditions under which its creation was required exist no more. The policy of the State in establishing another institution for chronic insane at Binghamton is to be deplored and condemned. The time has now come for devoting Willard and Binghamton to nobler purposes than their present legal position permits them to have, purposes for which they are already adapted. They should no longer be places for the custody and for the support merely of useless members of society, but they should be legally allowed to receive and treat the curable acute insane of their neighborhoods, whether public or private charges.

To more adequately show that the present system of separating the chronic and acute insane is unwise, and also unsuccessful, let me call attention to its failure in this State by means of the following facts:

THE CHRONIC INSANE IN SO-CALLED ASYLUMS FOR ACUTE INSANE.—From the annual reports of 1884 I find that the number of chronic cases admitted during the fiscal year into our State asylums for acute insane can be tabulated in this wise:

ASYLUMS.	ber admitte	admitted	in ad	P ch
Utica	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Poughkeepsie ..	[illegible]	90	[illegible]	68 08
Middletown	[illegible]	[illegible]	72	[illegible]

It will be seen from this table than an average of *nearly fifty-three per cent., or over one-half, of the admissions into our so-called asylums for acute insane are in reality chronic cases.*

This is the percentage of admissions alone, but the percentage of chronic insane present in any of these asylums, on any day in the year, is far higher than this. Happily, to illustrate this point, the Hudson River State Hospital can give us a statement which it has published for several years. It is a table showing the duration of insanity in the patients present on September 30, 1885.

[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
From three to six months	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
From two to three years .	[illegible]	[illegible]
From three to five years .	[illegible]	[illegible]
From five to ten years	[illegible]	[illegible]
From ten to twenty years	[illegible]	[illegible]
Over twenty years....	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
Totals	[illegible]	[illegible]

We gather from this table that out of 389 patients present in this asylum for acute insane, on that day, 314 were chronic cases. Out of the remaining 73 cases, that had been insane under one year, how many were general paretics, how many paralytics, how many demented, how many curable?

This may be taken as an example of the condition of patients, in this respect, in the other asylums for acute insane.

Can we not conclude from this that any one of these four asylums for acute insane will accommodate all of the acute insane of the State?

The State has caused accommodations for 1,800 acute insane to be made, when there are altogether only 300 to 400 cases at any one time.

THE ACUTE INSANE IN SO-CALLED ASYLUMS FOR CHRONIC INSANE.—Now, if we turn our attention to the institutions for chronic insane, we are startled to find here, too, natural law asserting itself, in spite of the effort to overcome it.

The Willard and Binghamton asylums for chronic insane both receive acute insane as patients.

They really act as district asylums for both acute and chronic insane. The Binghamton asylum has not yet been long enough established to have a large number of acute cases put down in its annual reports; still, a few are acknowledged. But on turning to the accompanying table, showing the insane in the five counties immediately about, and having easiest access to the Willard Asylum, we observe that out of their 278 insane, according to the State Board of Charities' last report (1884), 6 only

[1] Read before the State Medical Society at Albany, February 4, [illegible].

[2] See Dr. Edward Jarvis' article on the subject in the American Journal of Insanity, Vol. XII.

were in institutions supposed to receive acute insane, the remaining 272 being inmates of Willard.

Counties.	In Willard.	In other State asylums.
Ontario	15	2
Seneca	50	1
Yates	43	..
Schuyler	31	..
Tompkins	53	3
Totals	272	6

Some of the 6, perhaps all, may be upon private charge. Referring to the annual reports of Willard, it will be seen that every year some acute insane are admitted. There were thirty or more cases of acute mania and melancholia received there in 1884.

We have nothing to say against this, but everything in its favor. This is as it should be. The Willard Asylum should receive all the acute insane of the region that would find it of most convenient access.

It is the injustice of the present policy, which requires that an acute case of insanity, a mile from Willard, should be carried to distant Utica or Buffalo, when here is an asylum, charming in its surroundings, excellent and successful in its management, concerning which an eminent gentleman once said: "We failed to discover even the shadow of a reason why a person becoming insane in the neighborhood of this beautiful asylum should be sent to Utica because he was considered curable."

Of the so-called Districting of the Institutions for Chronic Insane.—Some may be aware that the State has been districted for the chronic insane.

The Binghamton district consists of twenty-one counties, and the asylum is not located in the district at all.

The Willard district consists of eighteen counties, six of which are in the northern part of the State, as far as convenient from the asylum.

Seventeen counties are exempted from the Willard Asylum act by the State Board of Charities, because they have asylums for their own chronic insane.

Four have been exempted by special statutes.

To point out the absurdity of this system of districting, I may here state that the Willard Asylum now contains more than 860 patients belonging to the Binghamton district; and that the Binghamton Asylum has patients from seven counties of the Willard district, and from seven exempted counties. Hence this division can hardly be said to be happy.

However, other more important facts reveal the necessity for change in the policy of the State with regard to the distribution of the insane, which we will contemplate in the following paragraphs:

The Depopulation of the Binghamton Asylum Possible.—It is probable that the Binghamton Asylum may become a total loss to the State through depopulation, for reasons which will presently appear.

The establishment of this institution so far outside of the district whose insane are required to be sent to it is a source of great inconvenience, loss, and sorrow to the people of the eastern part of the State.

Patients sent there are generally separated forever from home and kindred—people too poor to spare the time or money for so long a journey. Relatives are thus cut off from seeing those dear to them. Many patients are appreciative of the isolation awaiting them in the distant institution. The visits of friends are often of great remedial value in the treatment of insanity. Even this curative measure is denied them.

The cost of transfer of patients from the almshouses along the Hudson River and from the Poughkeepsie Hospital is in itself a serious burden to tax-payers. This has been estimated to be from thirty to one hundred dollars per patient. A little more than the latter sum would pay a year's board at Willard.

The Binghamton Asylum is so difficult of access to the counties constituting its district, that if the institution had been constructed at Baltimore, Buffalo, or Washington, the cost and trouble of transportion of patients and the inconvenience of visitation would be less than now. The county superintendents choose the most feasible route for the journey with their charges, which is by way of Albany and Utica—nearly three times the distance across in a straight line!

Take a map of New York and draw a line along the northern boundary of Jefferson and Lewis, the eastern of Lewis, Oneida, Madison, Chenango, and Broome, and thus divide the State into two nearly equal geographical sections, the eastern and western halves.

The twenty-nine counties of the western half of the State had (1880) an aggregate population of 1,706,728; the thirty-one counties of the eastern half, 3,376,143, or very nearly twice that of the former.

The western half paid in 1884 a State tax of $1,052,599.04; the eastern half, $3,529,579.84, or more than three times the amount paid by the former.

The western half has at present, approximately, 5,370 insane, the eastern, 11,252, or more than twice as many as the former.

The western half has five of the State asylums, with 3,500 beds, the eastern but two, with 750 beds.

If it be objected that the Auburn Asylum for Insane Criminals is for the benefit of the whole State, then the Middletown institution must also be excepted as having been built for the homœopaths of the whole State. Deducting, then, 150 beds for the former, and 400 for the latter, we have this remarkable fact:

The eastern half of the State, having twice the population, paying three times the amount of State tax, supporting twice the number of insane, is given by the State one asylum, with 350 *beds, while the western half is furnished with four asylums, having* 3,350 *beds!*

It may not be amiss to state here, also, that New York City and Brooklyn, which together pay more than half of the whole State tax, which have contributed more than half of the cost of the seven insane asylums of the State, and have often been called upon for the same proportion toward the maintenance of indigent and pauper lunatics in these asylums, have provided their own asylums and have always supported their own insane.

It is such unjust apportionment that rouses public opinion. The same popular voice is against the tearing of the insane from friends and dooming them to hopeless separation.

It is because of these things that the counties along the Hudson River must ultimately construct their own asylums for chronic insane, thus correcting in a measure these abuses, and at the same time bringing each institution into immediate and valuable commercial relation with the county that creates and supports it. Albany, Westchester, Ulster, and Dutchess Counties, having nearly seven hundred chronic insane in the asylums of the western part of the State, are already agitating such projects. Unless other provision is made for this section, this will soon be carried into execution, and the same be accomplished eventually in every other remote county of the Binghamton district, as the popular outcry for justice grows louder and the burden of caring for the insane grows heavier in each.

Do not these facts point to the depopulation of the Binghamton Asylum? With almost every county of its district providing for its own chronic insane, whence will come its patients?

Another feature in this injudicious transfer of the insane from the eastern to the western half of the State is that the county superintendents of the poor are often so much influenced by the piteous appeals of relatives that they will not remove the chronic insane from the Hudson River State Hospital. When unable, by appeal or influence, to win the officials to their cause, the friends will often pay to the county the difference in cost of maintenance at the acute and chronic institutions. Thus,

while it is cruel to refuse the supplications of unhappy relatives to keep their insane near them, it is, under the present state of things, also wrong that chronic and incurable cases should be supported for years in this hospital, to the extent that they are forced to be. It leads to the painful overcrowding, so apparent in this institution.

THE REMEDY FOR THESE EVILS LIES IN A PROPER SYSTEM OF DISTRICTING THE ASYLUMS OF THE STATE.—The remedy for the present system, or rather lack of system, is to divide the State into districts, each of which shall have an asylum, for both acute and chronic insane, as near its railroad centre as possible.

The total number of insane in the State is now about 17,500. October 1, 1884, the number was approximately 16,622, as compiled by myself from various State reports and from figures furnished me by the Census Bureau at Washington.

SHOWING APPROXIMATELY THE NUMBER OF INSANE IN THE STATE OF NEW YORK [illegible]

[illegible] [illegible]	[illegible]	[illegible]	[illegible]
58. Westchester	[illegible]	[illegible]	[illegible]
59. Wyoming	[illegible]	[illegible]	[illegible]
[illegible] [illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]

The key to districting the State is to make use of asylums already constructed, to form each district of counties having easy access to the institution, to apportion as nearly equally as possible the population and the number of insane, and to permit each asylum to care for both acute and chronic insane.

The advantages of this policy are :

1. The ease with which friends and relatives may visit patients.

2. The speed with which recent cases can be put at once under treatment.

3. The reduction in cost of transportation and maintenance.

It has been demonstrated that as the number of patients in an institution increases (at least as far as 2,000) the *per capita* cost of maintenance steadily decreases.

It is clear that our asylums for acute insane are receiving $4 to $4.50 weekly for cases supposed to be recent, when, as hereinbefore shown, an average of fifty-three per cent. of their admissions alone are chronics.

It is equally clear that Willard, receiving $2.42 weekly *per capita*, treats thirty or more cases of acute insanity annually at that price.

It is probable that the average *per capita* weekly cost of all the insane in all of these asylums under the new system need not exceed $2.50.

Having proven that any *one* of the State asylums built for the acute insane can accommodate *all* of the acute insane of the State, it is evident that each is already sufficiently able to care for the acute insane of its own proposed district, sufficiently beautiful in its surroundings, sufficiently luxurious in its architecture. Consequently the additional buildings necessary on the grounds of each should be of the plainest, most economical, yet durable character, because they are to receive the chronic and incurable cases.

Separate buildings for the various classes of patients should be constructed; for the trusty laborers, simple and substantial; for the violent, destructive, and noisy, strong, and with many single rooms; for the epileptic, for the paralytic, for the filthy, roomy and well ventilated; for the quiet and idle, plain, frugal, and homely.

The districts proposed are as follows :

1. The Buffalo or Western.
2. The Willard or Middle.
3. The Binghamton or Southern.
4. The Utica or Northern.
5. The Hudson River or Eastern.
6. The Plattsburg or Northeastern.

New York and Kings Counties constitute districts in themselves, as they take complete charge of their own insane, and will, in all likelihood, continue to do so. They are, therefore, not included in this division. If, however, justice should ever be done them, and their institutions be converted into State asylums, New York would be a district in itself, and a great asylum might be erected somewhere on Long Island to receive not only all the Kings County insane, but those from the rest of the island. With a New York district and a Long Island district added to the above, the system would be complete.

The Auburn Asylum for Criminals and the Homœopathic Asylum at Middletown are, for obvious reasons, not given districts, both having been built as special hospitals to accommodate certain classes of the whole State. Were it possible or just to force some of the counties to send all their insane to a homœopathic institution, the Middletown Asylum might be given a district consisting of Sullivan, Ulster, Orange, Rockland, and Richmond Counties, which have easy access to it, without interfering particularly with this plan of districting.

The Buffalo District.—The district to be accommodated by the asylum at Buffalo consists of eight counties, Niagara, Orleans, Genesee, Erie, Wyoming, Chautauqua, Cattaraugus, and Alleghany, having, according to the census of 1880, a population of 530,856, and an approximate insane population of 1,579. As will be seen, Buffalo is particularly well adapted to the wants of an asylum. Railroad centres radiate from it into every part of its district. It is like the centre of a spider web,

This institution has now 350 beds. It should be gradually enlarged to a capacity of 2,000, as the district demands it. It may be objected that some of the counties already have asylums, like Erie with its 300 patients. But even Erie County has patients now at Willard. It had last year a total of 190 insane in other institutions than its own.

The Willard District.—The counties constituting the Willard district are eleven in number—Monroe, Wayne, Cayuga, Livingston, Ontario, Seneca, Yates, Schuyler, Tompkins, Steuben, and Chemung—having a total population of 575,810, and an approximate insane population of 1,867. This institution has 1,800 beds, and is therefore almost large enough to meet the requirements of the district. It will need a small building for acute insane. Had we our choice of situations, the asylum would not have been placed so far as it is from a railroad centre. Still, for the territory as laid out, it is not so badly located. It lies nearly midway between the natural travel centres of the district—viz., Geneva, Ithaca, and Watkins Glen.

Here, too, it may be objected that Wayne and Monroe counties have their own chronic asylums, and we add that they are already overfull, and must overflow into Willard. Both have patients in Willard now, and their number must increase.

The Binghamton District.—The counties to constitute this district are the nine—Onondaga, Cortland, Chenango, Tioga, Broome, Otsego, Schoharie, Delaware, and Sullivan—which will find Binghamton of easy access, because that city is a good railroad centre for this region. These counties had, in 1880, an aggregate population of 425,284, and now an approximate insane population of 1,295. The institution has at present, I believe, a capacity of 800 beds. With the exception of the Willard, the necessity for increased accommodation for insane is greater in every other district of the State at present than at Binghamton. In time this asylum must be slowly enlarged to meet the increasing wants of the district.

The Utica District.—Utica is a railroad centre, and an excellent situation for an asylum. The counties which will find it of easy access are nine—Jefferson, Lewis, Herkimer, Hamilton, Oswego, Oneida, Madison, Fulton, and Montgomery—having in 1880 a total population of 450,909, and an approximate insane population of 1,464. The Utica institution has 600 beds, but should also be increased in size as required, to accommodate all the insane of its proposed territory.

The Hudson River District.—This district has a different conformation from the others, owing to its lines of travel, which lie chiefly along the great river flowing down its median line. The natural centre of this district must be along this river—the Hudson River State Hospital at Poughkeepsie—half way between New York and Brooklyn on the one hand, and Albany and Troy on the other, having a population of 3,000,000 within two hours' travel. This district should consist of fourteen counties, viz.: Schenectady, Albany, Rensselaer, Greene, Columbia, Ulster, Dutchess, Orange, Putnam, Rockland, Westchester, Richmond, Queens, and Suffolk. They had in 1880 a total population of 962,933, and at present an approximate insane population of 3,408. This is, of course, as before stated, exclusive of New York and Brooklyn. The capacity of the Poughkeepsie institution is but 350 beds, and hence needs enlarging to accommodate 2,000 patients very soon. The name Hudson River is given to this district, because it will be remembered that it contains two asylums, that at Poughkeepsie and the homœopathic institution at Middletown in Orange County. I can see no objection to the enlargement of the latter to accommodate chronic and incurable insane, when the district demands more room than the Poughkeepsie State Hospital, with its quota of 2,000, can furnish.

The Plattsburg District.—This region sends its insane at present to the Utica and Poughkeepsie institutions, chiefly, and has as yet no State accommodation. Plattsburg is the natural railroad centre of this territory, as will be seen upon the map. The location of an asylum elsewhere (in St. Lawrence County, for instance, as has been contemplated) would only complicate matters and make the districting of the State in the future still more difficult of accomplishment than now. This portion of the State is not yet as populous as it will be. But its seven counties—St. Lawrence, Franklin, Clinton, Essex, Warren, Saratoga, and Washington—aggregated in 1880 a population of 332,005, and its present number of insane is about seven hundred and eighty-nine. So remote are they from any hospital for the insane, that these unfortunates are kept at home as long as possible before the tedious journey to Utica or Poughkeepsie is undertaken. They are then brought either as moribund or chronic cases. At least this is the experience at Poughkeepsie as regards the insane from the remoter counties of the Plattsburg district. This part of the State should be relieved by the Legislature within the next few years. It may be worthy of suggestion that the Clinton prison at Dannemora, near Plattsburg, hitherto run, as I understand, at an annual loss to the State—and of little use for its present purpose—might be transformed into an asylum for this district.[1]

KAIRINE AND ANTIPYRINE.[2]

By J. HENRY FRUITNIGHT, A.M., M.D.,

FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, AND OF THE AMERICAN ACADEMY OF MEDICINE, ETC.

We are all aware of the close attention that has been devoted during the past decade, by the profession everywhere, to the subject of the reduction of high temperature. From the multiplied observations of these years it has been learned that an individual may tolerate an exceedingly high degree of temperature for a very brief period with comparative safety, and that the element of danger resides in the persistency of such high temperature. We all have most probably met with cases in which a very high temperature—possibly as high as 107° or 108° F.—existed for a very short time, and yet notwithstanding this high temperature the patient finally recovered. Had this high degree of fever, however, continued for a longer period of time irreparable disorganization of the blood must inevitably have occurred, resulting in a perversion of tissue metamorphosis which would terminate only with the death of the patient.

From these facts we are warranted in drawing the deduction that if we could procure an agent to hold in check the tendency to a high temperature in febrile diseases, one element of danger, viz., hyperpyrexia, could be held at bay, and to that extent a favorable issue of the case in hand might be prognosticated. It is not assumed that under these circumstances the remedy is to remove the cause or the specific *materies morbi* of the fever, and thus abort or cure the disease, but rather to reduce the pyrexia to a safer limit, the disease nevertheless running its usual course as regards duration. And this is exactly what is effected by some of the antipyretic methods and remedies recently employed. Your attention this evening will be called to two of the purely medicinal means used to effect this reduction of temperature—I refer to Kairine and Antipyrine. *A propos*, the title of this paper might in justice be written Antipyrine *versus* Kairine.

I shall allude but very briefly to the physical and chemical qualities of these drugs, dwelling especially upon their physiological action and therapeutical effects so far as known. Nor shall I weary you with detailed

[1] The paper was illustrated by six large maps of New York State, drawn by the author to represent the present state of things, and the method of districting he proposes.

[2] Read before the Northwestern Medical and Surgical Society of the City of New York, April 21, 1886. Specimens of the drugs described, in original packages, were exhibited to the Society for inspection.

clinical histories of cases, but preferably I will state, in general terms, the observations which I have made in different groups of cases and varieties of diseases, concluding with a summary of deductions derived therefrom.

Owing to the unwieldy complexity of the chemical appellations of both of these substances, names etymologically significant of their clinical effects and therapeutical applications have been coined for them. Thus kairine from the Greek adjective of the first and second declensions, *καιρίος-α-ον*, meaning appropriate, happening at the right time, etc., secondarily, mortal or fatal; and antipyrine from the Greek preposition *αντί*, against, and the Greek noun *πυρ*, fire, meaning against fire, and, secondarily, against heat or fever. Both words have sometimes been written without the final letter *e*, which is manifestly improper, because as the analogues of the alkaloids of belladonna, conium, nux vomica, opium, etc., which do possess the final vowel *e*, they should undoubtedly correspond with these latter in their orthography.

Both kairine and antipyrine are artificial productions, the results of researches in synthetic chemistry. It had been known for some length of time that when quinine is distilled with caustic potash a volatile nitrite base called chinoline (C_9H_7N) is obtained. Donath, who was the first to obtain the physiological action of this substance, demonstrated that in many of its effects it closely resembled quinine. Further experiments by proficient and renowned German chemists, particularly Fischer, of Munich, and Dr. Knorr, resulted in the discovery of kairine and antipyrine. From chinoline (C_9H_7N) kairine has been obtained by the processes of hydration, oxidation, and substitution—one or more atoms of hydrogen being replaced by one of the primary alcoholic radicals. In this manner two substances, known respectively as oxy-hydro-methyl chinoline ($C_9H_{10}NO,CH_3$) and oxy-hydro-ethyl chinoline ($C_9H_{10}NO,C_2H_5$), have been produced. The former has been distinguished as kairine *m*, and the latter as kairine *a* or *e*; but as the ethyl compound has latterly been more commonly used in practice, it is meant when the word kairine is used without such qualification.

From a hypothetical base closely allied to chinoline in its chemical properties and constitution, entitled quinizine, Dr. Knorr derived antipyrine, which is a dimethyl-oxy-quinizine ($C_{23}H_{12}M_4O_2$).

On page 493, vol. ii., of Ziemssen's "New Handbook of General Treatment," it is said: "It is interesting to note that most of the antipyretics belong chemically to the so-called aromatic group (derivatives of Benzol), a group which at the same time yields many of our best antiseptics. Thus carbolic acid, salicylic acid, benzoic acid, kairine, antipyrine, quinine, and the other alkaloids of cinchona are all of them members of this group. This fact tends to confirm a somewhat general belief that some, if not all, of our most efficient antipyretics owe this action to their antiseptic properties." As a logical conclusion to this reflection, I will venture to predict that in the future treatment of diseases of septic origin brilliant therapeutic triumphs will follow in the wake of the progressive development of this portion of the field of organic chemistry.

I will take up kairine first, merely because in its production and use it antedates antipyrine.

It was in the early part of the year 1882 that Filehne, of Germany, announced that a remedy had been found which would outrival quinine in its efficiency to reduce fever. The remedy was welcomed with much enthusiasm, and physicians hastened to verify or disprove the claims that had been raised for the new medicine. Kairine is a grayish-yellow, crystalline powder, easily soluble in water and alcohol, and of a bitter taste. It is true that the drug has the property of reducing a high temperature, and this it does very soon after its exhibition. My personal experience with the remedy is limited to its use in cases of typhoid fever. In the autumn of 1882 I made considerable use of kairine in about half a dozen cases of this disease. My experience with it in the last case of this series, however, led me to abandon it forever. I will detail my observations of the physiological effects of the medicine as revealed by its employment in these cases, and in the one last referred to in particular. I have given it in doses of only from grs. v. to grs. x., every three or four hours, watching its effects closely. It has, however, been advised by other observers to be given in much larger doses, and to be administered at one time. Its most marked physiological effect is its action upon the sudoriparous glands of the skin, and I therefore speak of it first. Kairine produces a most extraordinarily copious diaphoresis, which is accompanied by an excessive dilatation of the cutaneous vessels, and by an inhibition, or at least perversion, of their vaso-motor influences. This sweat, which is poured out under the influence of kairine, is cold and clammy.

At the same time its effect upon the heart and circulatory system is dangerously depressing, interfering with the tonicity of the cardiac muscle, and in consequence retarding the proper oxygenation of the blood, producing lividity and ultimately cyanosis of the general surface of the body, with threatening collapse of the patient. The rate of the pulse is reduced in frequency, as are also the respiratory movements, but in this reduction their arithmetical physiological ratio is not maintained. In other words, the respiratory movements are subjected to a more active reduction than is the rate of the pulse. This is a second element retarding the proper oxygenation of the blood.

Kairine, furthermore, has an injurious action upon the red blood-corpuscles, hindering them in their functions as oxygen carriers.

In my experience the remedy seems to obscure the lucidity of the intellect, possibly on account of changes in the cerebral circulation, and consequent malnutrition of the gray matter of the brain. The medicine is eliminated by the kidneys, imparting to the urine a dark-greenish hue. Frequently albumen may be detected in the urine after the administration of kairine. It very frequently produces nausea and vomiting, with headache and *tinnitus aurium*. It produced a dry, parched condition of the fauces in some of my cases. The effect of the medicine on the action of the bowels was negative. Its effects, when well marked, resemble those presented in cases of carbolic-acid poisoning.

Kairine, because of its easy solubility in water, has been administered hypodermatically, but with bad effects, for motor paralysis, with reduced sensibility, even to the point of complete anæsthesia, has sometimes followed this mode of administration of the drug. I have never given it to children, nor have I ever read or heard that it had been administered to them.

The literature relating to kairine is very meagre, consisting entirely of isolated observations scattered here and there through the various medical journals. In typhoid fever alone does it seem to have been used to any extent.

From its physiological effects we can safely affirm that it would be obviously injudicious, not to say dangerous, to administer it in pneumonia. The recorded observations, however, nearly all uniformly concur in condemning kairine as a dangerous and treacherous remedy. Thus kairine, by the strangely ironical aptness of its name, unwittingly given to it by its discoverer, was destined to be fatal or mortal not to the patient's fever alone, but to the patient himself as well.

In the summer of 1884 I had under my care two cases of acute phthisis in young girls, aged respectively sixteen and nineteen years. They were also examined by Dr. James R. Leaming, of this city, who concurred in my diagnosis. Furthermore, specimens of the sputa of both patients, which were microscopically examined by Dr. Welch, now of Johns Hopkins University, Baltimore, but then of Bellevue, revealed a large number of the tubercle bacillus of Koch. A brother of one of these patients,

who happened to be an excellently educated pharmacist was deeply interested in her welfare. This patient suffered extremely with daily evening exacerbations of fever, though everything was done to check them, but all without avail. I then recollected that I had read fragmentary but favorable reports concerning the efficacy of a new drug called antipyrine in reducing fever.

It also was first used by Filehne, in Germany, in the spring of 1884. It was in August of that year when I told the brother of my patient that I intended to resort to antipyrine in the treatment of his sister's fever, and requested him to procure some of the medicine for me. After many trials and much trouble he succeeded at last in obtaining from a wholesale drug-house, as a favor for me, about half a drachm of the drug, which was all that could be found in the whole city at that time. I administered it in five-grain doses every four hours, and succeeded in reducing the evening temperature about two or three degrees, but so soon as the supply of the medicine was exhausted the exacerbations returned as before.

At the meeting of this Society held in October, 1884, I reported my observations upon the effects of antipyrine in the case just cited. So far as I know these were the first *publicly* reported observations upon antipyrine in this city, and possibly in this country.

Antipyrine, which was first produced by Dr. Knorr, of Erlangen, occurs in the form of prismatic crystals of whitish color and of a somewhat bitter taste. It is very soluble in alcohol and water, but less so in ether. Its solutions are of neutral reaction. It is sometimes adulterated with quinine or sugar.

Like kairine, antipyrine has the property of reducing febrile movement. Its chief action, too, seems to be diaphoretic, though in my experience not to the extent observed when kairine has been taken. The augmented perspiration, unlike that excited by the ingestion of kairine, is warm and natural. This diaphoresis is also accompanied by a moderate dilatation of the cutaneous vessels.

It reduces the frequency of the pulse, but not the number of the respirations. Hence the process of oxygenation is not interfered with. The normal temperature will not be disturbed if the medicine be taken under such circumstances. When given to an individual free from fever there is a slight dilatation of the cutaneous vessels, which is proportionally increased if fever be present at the time of the administration of the remedy. When repeated doses have been given, the antipyretic effect will be manifested from four to eighteen hours thereafter, and this effect will persist so long as the administration of the medicine is continued, even lasting a considerable time after the final dose and actual suspension of the remedy. The frequency of the pulse is affected to a less extent than the temperature is. It very soon cleans and moistens the furred tongue of fever patients, and retains it so.

It is sometimes accompanied by a bright red, miliary eruption, which does not cause any inconvenience to the patient, and which occasionally disappears even during the continuance of the administration of the medicine. This eruption appeared in the case of acute phthisis, to whom I first gave the remedy.

I have never seen antipyrine produce the depressing effects which have been observed when kairine has been taken. It does not interfere with or affect digestion, very rarely disturbing the stomach, and having no bad after-effects. The cerebral functions remain unimpaired. The action of the bowels is unaffected by antipyrine. It is eliminated by the kidneys, having been found in the urine.

It can be administered either by the mouth or by the rectum with equally good results, and because of its easy solubility it is also adapted to hypodermatic use. For the same reasons it can readily be given to children.

Foreign authorities have recommended to give the remedy in one large dose at a specified time. I should hesitate a little to act upon this advice, for I have given it, as Dr. Leonard Weber of this city also has given it, in divided doses, ranging from grs. v. to grs. x., every three or four hours, continued over a prolonged period of time, with satisfactory and positive results.

I have used antipyrine very extensively since my first report, having prescribed it for both children and adults. I have given it particularly in those types of disease which have as a factor a tendency to a long-continued high temperature, as in acute pneumonia, typhoid fever, pelvic cellulitis, phthisis, etc., and without the occurrence of any unfavorable symptom or result. It has been given by some physicians in scarlet fever, acute rheumatism, pericarditis, and other febrile affections; but as I have relied on other remedies in cases of this character, I cannot speak from experience as to the action of the remedy in them.

In fevers of a malarial type and origin *quinine* is of course our main reliance; but during the paroxysm of fever of an intermttent or remittent, when the temperature was high, I have given antipyrine, with the result of reducing the temparature. In the interval I returned to the quinine and thus by this combination of therapeutic forces lessened the severity of the attack. I have given it thus to both children and adults who have been afflicted with these forms of fever.

In those diseases in which high temperature is not a dangerous or prominent feature, as in ordinary cases of diphtheria, cerebro-spinal meningitis, etc., I have never given it, nor do I think that it is needed in such cases. I may here incidentally remark that antipyrine has also been used as a hæmostatic in epistaxis. To hold in check the diaphoretic action of antipyrine, if it be too profuse, its administration may be guarded with atropine or belladonna.

Antipyrine excels all other means at present known for reducing the temperature of certain classes of febrile patients. It is a safe and prompt antipyretic, especially in pneumonia and typhoid fever. At the Fourth German Congress of Internal Medicine, held at Wiesbaden, April 8 to 11, 1885, a general discussion on antipyretics took place, and the general verdict of all the prominent speakers was exceedingly favorable to the action of antipyrine. Nevertheless, I should not countenance its use as that of a routine remedy. The *minutiæ* of its administration must be determined by the physician in charge for each individual case.

The general conclusions which can be deduced from these observations are as follows:

Firstly, kairine and antipyrine are both antipyretic, with marked diaphoretic action.

Secondly, kairine is not only an antipyretic, but a cardiac and nerve depressant as well, hence dangerous to use, and should therefore be discarded in practice.

Thirdly, antipyrine does not cure or eliminate the cause of the febrile movement, but moderates it in its intensity, thus modifying its phenomena and contributing to the recovery of the patient; and,

Fourthly, the diseases in which antipyrine is especially indicated are those which have been designated as self-limited, in which there is a tendency to the persistence of high temperature.

Salicylate of Soda and Salicin in Glycosuria.—Dr. O. V. Petersson reports in the *Upsala Läkareförenings Förhandlingar*, vol. xxi., No. 6, 1886, a case of diabetes mellitus speedily cured by the use of salicylate of soda in daily dose of from one to one and a half drachm, followed after a month by salicin in doses of two drachms pro die. In fifty-six days the daily quantity of urine fell from one hundred and fifty to fifty ounces, the specific gravity from 1.045 to 1.022, and the amount of sugar excreted from about seven ounces to zero. At the time of the report, four months had passed without any reappearance of sugar or increase in the amount of urine passed in the twenty-four hours.

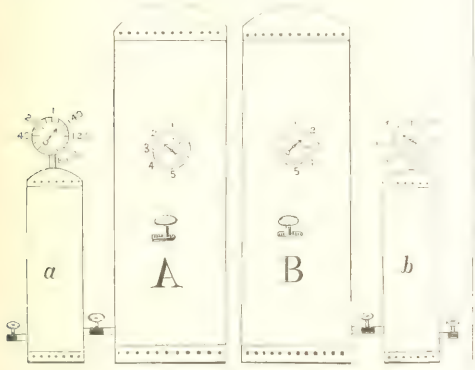
TREATMENT OF PHTHISIS BY DISPLACED AIR.

By W. C. SNEDEN, M.D.,

BROOKLYN, N. Y.

While this subject is attracting such wide-spread attention, I wish to contribute my mite toward alleviating the woes of my fellow-man.

In this short article I will endeavor to describe as briefly as possible an apparatus which will answer every purpose, which is not costly, and which can be owned by the operator, as it is not patented.



It consists essentially of two large air-receivers, for very moderate pressure, and two small air-receivers for very high pressure, such as are used for carrying compressed oxygen. A good air-pump is also needed—the "Novelty" being the best in my experience. One of the large receivers, *A*, is connected with the small receiver *a* by a tube with stop-cock. The large receiver *B* is connected with the small one *b* in a similar manner. Each of the receivers is furnished with a pressure-gauge.

If now the air is exhausted from *a* by means of the pump, we can diminish the pressure in *A* at will, by simply opening the stop-cock and allowing the air to flow from *A* into *a*. If we first force the air into *b*, at high pressure, we can increase the pressure in *B* by opening its stop-cock and allowing the air to flow from *b* into *B*.

By means of a flexible rubber tube leading from each of the large receivers, we can cause the patient to breathe the compressed air from *B* and expire it into the air of the room, or to breathe the same compressed air and expire it into the rarefied air in *A*, or to breathe the air of the room and expel it into either a denser or a rarer atmosphere in the receivers. The air at any of these densities can be easily medicated by vapor, spray, or any means ordinarily used.

The direction of the air-currents can be controlled by valves introduced into the mouth-pieces or into the tubes; or even by so simple an expedient as allowing the patient to alternately pinch the flexible tubes between his fingers and thumbs.

Pressure can at any time be increased or diminished in the small receivers by a few turns of the air-pump.

The cost of such an apparatus need not exceed two hundred dollars, and it can be constructed in any fair-sized town.

Catarrhal Headache.—Iodide of potassium is said to quickly relieve the dull headache so often accompanying an ordinary cold in the head. Two grains may be dissolved in a glassful of water, which is to be taken in little sips during half an hour. Dr. Davis recommends this simple remedy, and says he has hardly ever known it to fail.

Clinical Department.

A SHORT UMBILICAL CORD.

Dr. Charles P. Dolan, of Waterville, Minn., writes that he was called recently to attend an unmarried woman in confinement. He noticed as soon as the child was born that it was very weakly; it did not cry, but made a few feeble attempts to breathe. It was large and well developed, but was whiter than a new born infant usually is. On proceeding to cut the cord, the writer found that it was already divided; he immediately tied the end, but the child lived only an hour and a half. No great loss of blood was noticed during the progress of the labor. The cord was found to measure but twelve inches. It was reflected upon itself in two places, the adjacent surfaces being strongly adherent as though there had been an inflammatory process going on. The length of the cord, after the adhesions had been broken and the loops unfolded, was twenty inches.

CANCER OF THE MALE BREAST.

Dr. Sinclair Tousey, Jr., of Brooklyn, reports an operation for extirpation of cancer in the male breast, performed by Professor T. M. Markoe, at the New York Hospital. The patient was forty-five years of age, had always been strong and hearty, had never had venereal disease, and gave a negative family history. Twenty-five years ago a small tumor appeared under the left nipple, but it gave no pain, except when struck or pinched. Five years ago it began to increase in size, and shooting pains were felt in the breast. During the past year it had grown rapidly, and little pustules had formed and opened, discharging purulent matter. The tumor had attained the size of a small orange, was freely movable over the subjacent tissues, but was evidently malignant in its nature. It was rather flattened and biscuit-shaped, and there were numerous enlarged and indurated maxillary glands. Elliptical incisions were made, embracing the tumor, and it and the axillary glands and neighboring areolar tissue were removed. The wound was closed by catgut sutures, a single supporting stitch of silver wire being inserted to relieve tension. Upon examination of the tumor it was found to have invaded the entire mammary gland, which was considerably enlarged. The chief point of interest in the case was that it was one of cancer of the male mammary gland, an occurrence of some rarity. Of 102 cases of cancer of the breast recorded by Dr. S. W. Gross, only two were in the male subject, and very nearly the same proportion has been observed by other investigators.

The Foochow Medical Missionary Hospital.—We have received the fourteenth annual report of this institution for the year 1885. The hospital is under the care of Dr. H. T. Whitney, with three native assistants. Two of the native assistants rendered such valuable aid in the army during the trouble with the French, that they were promoted by General Tso Tsung Tang to the fifth and sixth degrees of military honors. The number of patients treated in the hospital was 604, with 334 cures, and in the dispensary 3,260, making a total of 3,864. The number of surgical operations performed, including 205 teeth extractions, was 425. The total expenses of the hospital, including wages and medical supplies, amounted to only $746.46. The religious work consisted in daily morning prayers in the hospital, and a short service on Thursday and Sunday afternoons. In the dispensary a regular preaching service is held previous to dispensing medicines. The report states that "at least five dispensary patients became interested in the truth during the year, and many more were led to see the superiority of Christianity over their own false religions."

Progress of Medical Science.

Calomel in the Treatment of Dropsy.—In the case of a patient suffering from dropsy, to whom, for other reasons, mercury in various forms had been given, Dr. E. Jendráfsik noticed marked diuresis and rapid disappearance of the anasarca after the administration of a few small doses of calomel. He was induced by this to try the drug in other similar cases, and met with great success. The calomel was given in doses of three grains, from three to five times a day, larger amounts being inadmissible on account of the action upon the bowels. The increase in the urinary secretion began about the second day and soon became excessive, subsiding again to the normal in from five to fourteen days. After the polyuria had once become established, a continuance of the calomel seemed to be productive of no good results. The amount of diuresis did not depend apparently upon the size of the dose of the calomel, but rather upon the extent and degree of the œdema. Experiments upon healthy individuals, as well as upon a patient with pleuritic effusion, were without result, thus proving, apparently, that the drug did not act as a renal irritant. The action upon the heart was also very slight, and, according to the author, purely secondary, and due to the favorable influence upon the circulation resulting from the reduction of the dropsical effusion. Dr. Jendráfsik thought that the diuresis was caused solely by the taking up of the fluids from the tissues by the blood. To prevent stomatitis the author ordered a mouth-wash of potassium chloride, or gave the drug internally in doses of twenty to twenty-five grains per diem. Several cases are related in which excellent results were obtained by the use of calomel.—*Deutsche Medicinal-Zeitung*, May 6, 1886.

Treatment of Lupus.—Professor Bertarelli, of Milan, recommends strongly resorcine in the treatment of lupus. Incorporated with vaseline (equal parts) and applied to the surface of the disease, it produces in a short time a healthy action, without provoking the slightest pain or irritation of the neighboring parts. The cicatrices are smooth, and of the color of the surrounding skin.—*Medical Press and Circular.*

An Unusual Source of Lead Poisoning.—A physician was called to see a child who had been treated unsuccessfully by a number of medical advisers for colic. He found an infant five weeks old, rather emaciated, whose skin was of a bluish color, continually crying, with feet and hands drawn together. The physician sought everywhere for the cause of the disease, finding none until he happened to notice the nurse's face, where he at once saw the explanation of the trouble. The nurse had a wonderfully pretty pink and white complexion, but the physician drew his finger across her face and found it covered with a greasy lead paint. The nurse confessed to having used cosmetics for a long time for her complexion. She was forbidden to do so, and the child recovered, with appropriate treatment, in a few days.—*St. Petersburger Medicinische Wochenschrift*, No. 8, 1886.

Rheumatismal Nodules.—At a meeting of the Hospitals Medical Society of Paris (*Annales Médico-Chirurgicales*, No. 3, 1886), M. Guyot presented a patient having a number of little nodosities in the subcutaneous cellular tissue and certain muscles which closely resembled gummy tumors. They had grown very rapidly until they were as large as hazel-nuts, at which size they remained stationary. In order to ascertain the nature of these little tumors, M. Guyot administered the iodides, but met with no result. He then tried salicylate of soda and had the satisfaction of seeing them rapidly disappear. M. Lallier said that such cases were not of great rarity. The tumors were to be distinguished from those of syphilitic origin by their rapid growth, the pain attending their evolution, and the ecchymotic tinge of the skin covering them.

A Case of Phonomimesis.—Dr. I. I. Pantyukoff reports, in the *Russkaya Meditsina* of March 16, 1886, a curious case observed by him in the military hospital at Kief some years ago. The patient was a young soldier who involuntarily reproduced with automatic exactness every sound which was made in his presence. His face wore a listless expression, the eyes were closed, and consciousness of his surroundings was apparently dulled, though not entirely extinguished. Words in foreign languages, snatches of songs, the sound of a violin or harmonica, all were echoed with accuracy by his voice; while stamping of the feet, clapping of the hands, and cracking of the knuckles were also imitated by the patient, even though he was lying on his back and the sounds were nearly drowned by other noises. It was wonderful, the writer states, with what exactness every kind of noise was reproduced by this human phonograph, and all sorts of sounds mixed up together were repeated each with its exact intonation and pitch. The patient was under the care of Dr. N. I. Shtcherbina, director of the psychological department of the hospital.

Bilateral Ranula Cured with Pilocarpine.—In a case of occlusion of both Wharton's ducts, which, distended and filled with saliva, formed two large pyriform tumors, one on either side of the frænum linguæ, Dr. G. Soffiantini conceived the idea of using pilocarpine in order to overcome the obstruction. He reasoned that the sudden and abundant increase in the secretion of saliva would so greatly increase the pressure that a passage would be forced through the ducts. A single hypodermatic injection of one-sixth grain of the hydrochlorate of pilocarpine resulted in the reduction of the tumors to one-half of their former size, and a second injection of a like amount cleared out the ducts completely and resulted in a cure.—*Lo Sperimentale*, April, 1886.

Compensatory Hypertrophy of the Kidney.—The following are the conclusions arrived at by Dr. Lorenz from a number of experiments upon animals (*Zeitschrift für klinische Medicin*, vol. x., Nos. 5 and 6): 1. Compensatory hypertrophy of the kidney consists chiefly in an increase in the cortical substance, although there is also a slight degree of hypertrophy of the medullary portion. 2. The enlargement of the cortical substance is due to: (*a*) Hypertrophy and hyperplasia of the glomeruli in growing animals, but simple hypertrophy in adult animals which have attained their full growth; (*b*) the convoluted tubules are enlarged throughout, the epithelial cells being especially increased in all their dimensions, and their calibre is widened. 3. The slight enlargement observed in the medullary substance is due only to a dilatation of the lumen of the straight tubules, no increase in size of the epithelial cells being noted. 4. The existence of hypertrophy of the connective tissue and of the capillaries could not be determined with certainty.

The "Dead-finger" Symptom in Bright's Disease.—This is a sensation similar to that experienced when the finger is immersed in snow, or exposed to a great degree of cold. The patients complain of formication, painful sensations, and cramps in the fingers, and sometimes the finger-tip becomes anæmic, white, and numb. This symptom is usually of very brief duration. In one patient it will last a few seconds only, but will reappear whenever the attempt is made to grasp any object; in another its duration will be for five or six minutes, and it will be noticed to recur at longer or shorter intervals, as one or two days or a week; finally, a third will recall its appearance on a single occasion only during the course of his disease, when it may last for a quarter of an hour. The symptom is localized now in one finger, now in another, the little finger being the one most frequently affected, the middle, the ring, the index finger, and the thumb coming next in the order of frequency. The phenomenon may appear at the beginning of Bright's disease or near its termination, but is of

greater diagnostic importance in the former case, since the other symptoms of the affection may at this time be insignificant or even absent. As to the pathogenesis of this sign Dr. Soyer believes that it is the first degree of local asphyxia of the extremities, and regards it as allied to symmetrical gangrene as sometimes observed. —*Giornale Internazionale delle Scienze Mediche*, No. 3, 1886.

Concealed Penis.—Dr. R. H. Bayler reports the following condition found in a child two weeks old: The root of the penis was attached firmly to the pubis, but the body of the organ could not be seen, being deeply buried under a continuation of the abdominal muscles and skin. The scrotum was not divided into two lateral halves by the raphé, but resembled a large bag. After examining the scrotum carefully the two testes were found, and between them the penis could be distinctly felt. The glans penis made its exit about the middle of the scrotum, between the testes. It had the usual appearance and was covered with the prepuce, and at the apex the meatus urinarius was seen. The child passed water freely during the examination.—*Virginia Medical Monthly.*

Treatment of Asphyxia of the New-born.—Dr. Wm. L. Reid, writing in the *Glasgow Medical Journal*, describes the various methods in vogue for the resuscitation of children born asphyxiated. They are nine in number. 1. Marshall Hall: The patient is turned face downward so as to press on the chest and cause expiration, then turned on the side so as to free the chest from pressure and produce inspiration by means of the elasticity of its walls. 2. Howard: The arms are extended, the wrists being brought together over the head, and the chest is thus expanded. The lower ribs are then alternately pressed on and relieved from pressure, so as to cause expiration and inspiration. 3. Sylvester: The arms are raised upward and forward for a few seconds, and then pressed firmly down against the sides of the chest. By means of their muscular attachments the ribs are raised and air sucked in, which is expelled again when the arms are brought down. 4. Pacini: The feet are fixed, and the operator, standing with the head against his own abdomen, seizes the arms at the axillæ and pulls the shoulders upward and forward, then allowing them to return to their former position. 5. Bain: The shoulders are raised by lifting the body a foot off the table by seizing its hands. They are then allowed to fall back again, thus causing alternate expansion and contraction of the thoracic cavity. 6. Schucking: Like Sylvester's, except that he carries the arms outward as well as upward. 7. Schuller: The operator puts his fingers under the edges of the ribs and pulls them up, afterward depressing them. 8. Schroeder: The body is supported by one hand placed under its back, allowing the head, shoulders, arms, and pelvis to fall backward, with the view of producing inspiration, expiration being caused by sharply bending the body forward so as to compress the chest and abdomen. 9. Schultz: The child is suspended a few inches from the floor by the two index-fingers placed in the axillæ from behind, the thumb lying loosely over the front of the thorax, and the other fingers spread also loosely over the thorax behind, the head being supported against the edges of the ulnar bones. Without delay, in this position, the child is swung sharply upward, until the operator's arms are extended horizontally; then the upward movement is continued more gently so as to bring the legs slowly past the perpendicular, and allow them to sink quietly against the front of the child's body. The weight of the latter is now supported by the thumbs in front of the thorax, and the chest pressed on all round by the fingers, and its arms laid against its sides. This compression through the diaphragm below, and the fingers all round, causes aspirated fluids to flow freely from the mouth and nose. After being retained in this position a few seconds, the body is swung smartly down again into its former position, taking care that now there is no compression of the chest, either before or behind, but simply a suspension of the child on the index-fingers. During this movement the contents of the abdomen fly away from the diaphragm, and, dragging it down, enlarge the chest from below. At the same time the arms are separated from the sides, and by their muscular attachments drag the ribs upward, and in this way air is sharply drawn into the lungs. These movements are continued every four or five seconds, but when a considerable quantity of fluid continues to come from the mouth and nose, the movement of expiration is to be prolonged.

Tertiary Syphilitic Arthritis.—M. Gangolphe has recently published a paper on osteo-arthritis occurring in tertiary syphilis, the conclusions at which he arrived being based upon the morbid changes found in five cases, two of these having been examined by the author himself; the remaining three are quoted from Lancereaux, Méricamp, and Schüller. The author is of the opinion that the existence of only one kind of tertiary joint-affection (the osseous form) is actually proved; but cases published by Gies, Schüller, and Virchow point to the supposition that there exists another variety of joint-affection, characterized especially by chondritis with star-shaped cicatrices and nipple-like projections, thus producing a change bearing some resemblance to the lobula ion seen in the liver when attacked by atrophic cirrhosis. The lesions in osteo-arthritis present different characters, according to the period at which they are examined. The affection begins by the formation of a gumma in or near the epiphysis, and, unless the growth remain encysted, it ends by perforating the cartilage. The synovial cavity then becomes filled with sero-purulent fluid. The morbid change extends more and more both in the bone and the cartilage, and the gaps thus resulting from loss of substance become lined by a smooth reddish new membrane. The ligaments remain intact. The synovial membrane is thickened, but without fungosities, and the absence of these, the adhesion of the remaining cartilage to the subjacent tissue, the absence of Koch's bacilli, and the microscopic appearances, serve to distinguish the syphilitic from tuberculous lesions. Further distinctions are the absence of any considerable sequestrum, and of patches of eburnation of whitish color which frequently accompany osseous tubercle. Recovery may take place under specific treatment, or even spontaneously, but deformities of the articular ends of the bones often occur; such deformities are clearly distinct from those due to rheumatic arthritis. From a clinical point of view, syphilitic osteo-arthritis is characterized by effusion of fluid variable in kind, and often small in quantity, by crackling of the joint, by the multiplicity of joints attacked, and by the relative indolence of the lesions. The joint indeed retains its normal functions to a degree that renders it difficult to suspect the extent of the disorder during life. In some cases there is more or less deformity of the articular extremities, and sometimes swelling of the diaphysis. Fibrous anchylosis may also result from osteo-arthritis. In consequence of the marked tendency to spontaneous recovery operative interference is very rarely indicated.—*London Medical Record*, April, 1886.

Vicarious Menstruation from the Ear.—Dr. Stephenoff relates the case of a girl, seventeen years of age, a pupil in the normal academy of Moscow, who suffered from various nervous symptoms at her first menstrual period. She became exceedingly irritable, being especially excited when she heard singing, and had paralysis of the lower extremities. The paralysis gradually disappeared, and the girl did not menstruate again, but at each returning period had vicarious hemorrhages, first from both ears, and then from the left one only. The bleeding lasted for one or two days, and was accompanied by palpitation and pain in the region of the heart. The patient was stout, but anæmic, had much headache and

palpitation of the heart, was subject to fainting spells, and there was hyperæsthesia over the lower part of the spinal column, and anæsthesia of the lower extremities. Examination of the ears revealed nothing abnormal. The hearing was normal, except that it was slightly weakened in the left ear just before and during the hemorrhage. As the drum-membrane was intact the bleeding must have come from the external auditory canal, although the writer was not able to assure himself of this fact.—*Centralblatt für Gynäkologie*, March 27, 1886.

Muscular Anomaly of the Arm.—At a recent meeting of the Section on Anatomy of the Irish Academy of Medicine, Dr. Heuston presented a communication on a curious combination of abnormal muscles in the upper arm (*Dublin Journal of Medical Science*, April, 1886). It consisted of two sets of muscular fibres, the lower of which passed from the latissimus dorsi across the first stage of the brachial artery, while the upper, taking origin from the cartilages of the sixth and seventh ribs, crossed the axilla and third stage of the axillary artery, to be attached with the former set of fibres into a broad triangular tendon, the external border of which passed over the biceps and pectoralis major to be attached into the deltoid, while from its inferior angle a tendon passed to the internal condyle of the humerus. Dr. Heuston considered the lower set of fibres to be an example of the Achselbogen, while he considered the upper fibres to be an example of the chondro-epitrochlearis, the tendon attached to the internal condyle being the proper tendon of those fibres.

The Rôle of the Nervous System in the Causation of Vitiligo.—Dr. A. H. Ohmann-Dumesnil, writing in the *St. Louis Medical and Surgical Journal* for March, 1886, asserts that the rôle of the nervous system in the causation of vitiligo is a very considerable one, and he says that this fact should contribute largely to an effort on the part of all who meet these cases to treat them, and not turn away the patients with the assurance that nothing can be done. He recapitulates the arguments in favor of this view as follows: 1. Analogous cases, where pigment disturbance is known to depend upon some functional or organic trouble of the nervous system; *e.g.*, blanching of the hair through mental emotion, and the loss of pigment in the anæsthetic spots of leprosy. 2. Where there is excess of pigment due to nervous influence, as in chloasma caused by nervous reflex action due to uterine and hepatic troubles. Both of these forms of disturbances of pigment are merely variations of a certain type, of which vitiligo is another variation, the three being types of loss, increase, and displacement of pigment. 3. The distribution of the disease is another very strong presumption in favor of its nervous origin in a considerable number of cases. Vitiligo is, as a rule, symmetrical, and quite often unilateral. 4. The concomitant nervous phenomena seem to corroborate the idea that vitiligo is often directly traceable to a neurotic origin, the majority of patients being subject to nervous affections or having a family history of neurotic troubles. 5. The effects of nervines have been quite marked in some cases. 6. The use of the galvanic current has been attended with success in treatment. 7. The nerve-alterations found in this disease are marked in some cases.

Puerperal Convulsions Without Albuminuria.—Dr. Vuccino reports the case of a woman of ordinary good health, except that she had occasional attacks of hysteria, who in the fourth month of pregnancy was seized with intense frontal hemicrania, recurring every day. When at the end of the sixth month, she was awakened one morning by a severe pain in the head, which was followed by a slight convulsive attack limited to the upper extremities. Later in the day the author found her in general convulsions, unconscious, and with bloody foam coming from her mouth. The pulse was small and hard, the urine was, and remained, free from albumin. After all other means had failed it was determined to induce labor, and this was accomplished by means of warm-water injections. A dead child was expelled from the uterus, and the convulsions ceased immediately. The woman remained perfectly well until the eighth month of her next pregnancy, when she was seized with convulsions even more severe than before. Chloral and chloroform were again tried without effect, and it was again found necessary to induce labor. The convulsive seizures did not reappear until the second month of the succeeding pregnancy, when they returned in slight degree, and ceased upon the occurrence of spontaneous abortion. The urine remained always normal.—*Journal de Médecine de Paris*, April 4, 1886.

Detection of Blood in the Urine.—M. A. Luchini proposes the following method for determining the presence of blood in the urine. One drop of acetic acid and forty-five minims of chloroform are added to two and one-half drachms of the suspected urine. The phial is to be well shaken and then set aside to stand for a time. If the urine contain blood the chloroform, which settles to the bottom, will have a reddish tint, the depth of which will vary according to the amount of blood present.—*Revista Médica de Sevilla*, March 31, 1886.

A Unique Case of Hernia.—Dr. R. H. P. Ellis reports in the *Maryland Medical Journal* of April 17, 1886, the case of a man who was seized with pain in the lower part of the abdomen after having lifted a moderate weight. He was found to have a small inguinal hernia, which was apparently reduced without much trouble. On the two following days the patient was very comfortable, but on the third day, having had no movement from the bowels, he took a dose of castor-oil, supplemented by an enema. This had no effect, and the following day symptoms of intestinal obstruction appeared. The hernia had apparently been entirely reduced, and no tumor could be felt at the abdominal ring. It was determined, however, to make an exploratory incision at this point, and, after a few touches of the scalpel, the search was rewarded by the finding of a small button-like portion or knuckle of intestine, firmly held within the abdominal ring. The operation was followed by a favorable modification of all the symptoms, but on the second day symptoms of general peritonitis supervened, and the patient died four days after the operation.

Rectal Exploration in Hip Disease.—Dr. Arnold Schnitz, writing in the *Centralblatt für Chirurgie*, of March 13, 1886, calls attention to the value of examination by the rectum in doubtful cases of morbus coxarius. He relates several cases in which he was enabled to clear up uncertain points in diagnosis, and to determine the seat of the disease. In one case of vertebral caries, in which coxitis was also suspected, rectal examination revealed the presence of an abscess on the opposite side of the cotyloid cavity. The author somewhat rashly concludes that he will always in future examine per rectum every case of hip-joint affection which he is called upon to treat.

Iodoform in Gout.—Professor Testa, assuming that iodoform fulfils all the desired conditions in the cure of gout, since it accelerates the processes of oxygenation, increases the secretion of urea, and diminishes the proportion of uric and oxalic acids, has employed it in several cases of this affection. The dose varied from one to four grains. This use of iodoform gave excellent results. The attacks of gout became less frequent, they were diminished in intensity, and their duration was shortened. The author says it is contra-indicated, or, at least, should be administered with great caution, when the gout is complicated with disease of the kidneys, for, as in such cases it is not completely eliminated from the system, it may give rise to untoward symptoms.—*Le Moniteur Therapeutique*, April 5, 1886.

The Etiology of Scarlatina.—At a meeting of the London Medical Society Dr. Hingston Fox read a paper with the object of proving that scarlatina and diphtheria resulted from absorption of a specific poison by a previously inflamed tonsil. According to this gentleman, the physiological rôle of the tonsils is to absorb the surplus saliva, and in doing this various poisons were apt to pass into the system.—*Medical Press and Circular*, April 7, 1886.

Hemic Changes after Extirpation of the Spleen.—At the last sitting of the Congress of Russian Physicians, Dr. Winogradoff read a paper on the above subject. He had operated on a dog which had previously lived in the yard on an irregular and sometimes insufficient diet. After extirpation of the spleen, which was performed six years ago, the animal was kept in the open air chained, on a good mixed diet and in a good kennel. Up to the present he has kept lively and in good spirits. Examination of the blood showed that in the first year after the splenotomy increase in the blood-serum was noted until the year 1885, when the quantity diminished, but it again returned to the normal. The red blood-corpuscles increased in the second and third years after the operation; lately they had diminished, however, and the microcytes were few in number. The specific gravity of the blood was 1.054, that of the serum 1.026. The quantity of hæmoglobin, which had already diminished at the end of the first year, varied a little during the later years, and had again sunk recently. It appeared noticeable that the production of hæmoglobin had diminished. At first the production was rather more active, but it always remained below the normal, and fell again latterly, from which the experimenter drew the conclusion that the compensatory activity of other organs gradually diminished, and that the dog would eventually die of gradually increasing deficiency of hæmoglobin, as, notwithstanding abundant food and fresh air, he was steadily losing weight. —*Medical Press and Circular*, March 31, 1886.

The Patellar Reflex in Locomotor Ataxia.—Hirt reports three cases of tabes dorsalis (with one autopsy) in which the patella tendon reflex was unaffected, and in one case it remained up to the time of death. Westphal has also, he says, reported two similar cases. In a fourth case Hirt noted the preservation of the knee-jerk on one side, while it had been absent for over eighteen months in the other leg. He believes that, even with extensive degeneration of the posterior columns of the cord, the part regarded by Westphal and others as the anatomical seat of the patellar reflex may remain intact.—*Aerztliches Vereinsblatt*, March, 1886.

External Urethrotomy in the Treatment of Retention from Enlarged Prostate.—In the *Centralblatt für Chirurgie*, Professor Braun, of Jena, advocates external urethrotomy for the relief of retention of urine due to prostatic disease associated with false passages, when it is found impossible to introduce a catheter by the usual way into the bladder. Forcible catheterism is an uncertain and dangerous method, and to capillary puncture and aspiration above the pubes it is objected that such treatment is troublesome to the patient and painful, that it has to be frequently repeated, that it does not allow necessary injections into the bladder in cases of strongly alkaline urine, and, finally, that it is not free from risk. The danger consists, not in direct injury to the peritoneum, but in the risk of inflammation of the connective tissue near the bladder from the penetration of decomposed urine into the punctured wound, and of extension of this inflammatory action to the peritoneum. The same objections apply to the method of puncture and retention of the cannula. External urethrotomy allows a constant and free discharge of urine through a retained catheter of full size, and also thorough and repeated cleansing of the bladder by injections, which would diminish or possibly dispel altogether the infective properties of the urine. Such treatment will also enable the surgeon, in the not uncommon case of a complication of prostatic hypertrophy with vesical calculus, to discover and remove the latter. In dealing with the objection to external urethrotomy as being too severe an operation in comparison with suprapubic puncture, Braun points out that the existence of false passages passing through the prostate into the cellular tissue between the bladder and rectum, or into the cavity of the bladder, may cause suppuration and pyæmia, and therefore indicates prompt and effectual treatment, favoring an uninterrupted flow of urine, and a ready discharge of any collection of pus.

Acute General Œdema.—Professor Da Costa had at his clinic recently a case of acute general œdema without kidney, heart, or blood affection. He considers this a case of what the old writers called inflammatory œdema, and to which he applies the term catarrhal œdema. The lesion is principally in the areolar tissue. He recovered in about a week, under an active diaphoretic treatment. At first ammonium acetate was given, afterward jaborandi.—*College and Clinical Record*, April 1, 1886.

Silicate-of-Sodium Jackets.—Dr. S. T. De La Mater, writing in the *New England Medical Monthly*, says that he has found sodium silicate a most excellent substitute for plaster-of-Paris in the treatment of lateral curvature of the spine and Pott's disease. In using it for the jacket in spinal disease, he first fits the undershirt snugly to the body, and over this places a thin layer of cotton wadding. He then rolls one layer of a plaster bandage around the body, and over all three or four thicknesses of cheese-cloth saturated in silicate of sodium. The chief advantage of this application is its lightness, the jacket so constructed not weighing more than six or eight ounces, and yet being sufficiently firm to give perfect support. Dr. De La Mater cautions his readers against potassium silicate, which is often substituted for the sodium. The latter is, when pure, of a light amber color, having the consistency of syrup, while potassium silicate is pale white.

Urethran.—Dr. A. S. Myrtle writes in the *British Medical Journal* that he has used urethran in over fifty cases, in the past four months, as a sedative and hypnotic, and his experience of its action encourages him to recommend the drug strongly, believing that, in certain cases, it will prove of great value. The cases in which he prescribed it were of the usual run of every-day practice, where a sedative or hypnotic was required: general restlessness, sleeplessness, neuralgia, catarrh, certain forms of skin-affections with great irritation, also rheumatism and gout. Many of his patients had some peculiarity of constitution which prevented the use of opiates of the usual type; and it is in this special class that the writer thinks urethran will prove of great value. One gentleman, who had suffered from insomnia for weeks, and who could not tolerate opium or chloral, took fifteen grains at bedtime with the most perfect result. He wrote: "The sleep caused was most pleasant and refreshing. I awoke without a headache, with appetite for breakfast, and what was equally agreeable, there was no interruption to any of my functions." Similar testimony was given by the majority of patients, who had taken full doses to produce sleep. In smaller doses its action is less marked, still it is decidedly calmative and agreeable, causing no unpleasant effect, such as nausea, flatulence, constipation, or headache. It does not affect the nerve-centres of circulation or respiration, but spends itself on the cerebrum. It possesses, therefore, Dr. Myrtle says, great advantages over the older and valuable sedatives, which have certain evil influences, especially in exceptional cases. Given in gout and rheumatism in full doses, alone or in combination, it has the great advantage over morphia of not interferring with the action of the bowels or kidneys; besides, it is not unpleasant to the taste.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 5, 1886.

IS TETANUS AN INFECTIOUS DISEASE?

IT needs no argument to prove that a better knowledge of the cause and nature of tetanus is greatly to be desired, bearing as it does so directly upon the treatment of the disease. For, until we know what tetanus really is, all treatment must be purely empirical and symptomatic. There are a sufficient number of well-authenticated cures of the disease on record to prove that the affection is not necessarily fatal, and could we but discover what it is, and what is its cause, we should be in a far better position to apply our remedies intelligently and with a definite aim, and should doubtless be able to save many more of our patients.

The fact that, in a very large proportion of cases, tetanus follows the receipt of a wound, has led several observers in recent times to regard the affection as dependent upon the introduction of some virus from without. Roser was one of the first to advance this theory. The earliest experiments by inoculation of animals were without result, possibly because they were made with dogs, which are said by Rosenbach never to suffer from tetanus.

At the Fifteenth Annual Meeting of the German Surgical Society, held recently in Berlin, Rosenbach presented an interesting paper on this subject, in which he gave the results of a number of experiments performed on guinea-pigs and mice. A man was received into the Göttingen clinic suffering from tetanus, consequent upon gangrene of the feet, from which he died. The author took some small pieces of tissue from a portion of the foot not invaded by gangrene and inserted them under the skin of the thigh of two guinea-pigs. The animals soon exhibited marked tetanic symptoms. From these other guinea-pigs were inoculated in a series, one from the other, and then the virus was transferred to mice, all the animals dying eventually with unmistakable symptoms of tetanus. He was not able to obtain pure cultures of any single micro organism, but he succeeded in causing the disease by inoculations with a mixed culture carried to the fourth generation. By exposing the cultures to a certain temperature he was able to destroy all forms of microbes except two varieties of bacilli, and as these cultures were still capable of exciting tetanic symptoms he drew the conclusion that it was to the presence of one of these two forms that the disease was due.

Assuming that tetanus results from the introduction of a bacillus into a wound, the next question demanding solution would be from whence the micro-organism comes. As bearing on this point, the experiments of Nicolaier and Flügge are interesting. While engaged in a study of the micro-organisms found in garden soil, they discovered that a culture of a certain form of bacillus, when injected into the tissues of rabbits, guinea-pigs, and mice, was capable of causing symptoms identical with those of tetanus. Socin, of Basle, has also seen similar symptoms produced in mice by the introduction beneath the skin of a little earth taken from the garden.

There are numerous facts which seem to lend weight to the theory of the infectious nature of tetanus. One of the most striking of these is the case mentioned by Betoli, of three slaves who died of tetanus after eating the flesh of a bull which had perished from the same disease. Another is that the affection does not follow immediately upon the receipt of a wound, but that a certain period of incubation, varying from a few hours to two or three weeks, is present. This, it is true, might be equally applicable to the theory of a lesion starting from the peripheral nerves and travelling to the medulla, but such a lesion is not found on post-mortem examination.

The geographical distribution of the disease might also be brought forward as an argument in support of the view of a micro-organism residing in the soil. Tetanus is most prevalent in warm climates, although by no means confined to tropical countries, and it is sometimes very common in certain isolated communities, especially those living on islands and separated by natural barriers from the rest of the world. It is said to be very prevalent on the eastern end of Long Island, and if anyone succeeds in isolating Rosenbach's bacillus from the fish manure, which is so thickly spread over that unfortunate region, the theory of infection in tetanus will receive a strong impetus.

But there is another theory which can, perhaps, be made to fit in with these facts as easily as the one which we have just considered. We refer to the doctrine of leucomaines recently presented so ably before the Paris Academy of Medicine by M. Gautier. It might easily be conceived that a form of decomposition in the wound should result in the elaboration of certain animal alkaloids, producing symptoms similar to those caused by strychnine and some other alkaloids of vegetable origin. Doubtless M. Peter and his followers will not let pass such a favorable instance as this for the support of their views.

THE DIAGNOSIS OF DEATH BY DROWNING

IT is stated by many writers, and is the pretty general belief of those having but a moderate acquaintance with medico-legal literature, that it is impossible in many cases to determine whether, in the case of a body found in the water, death resulted from drowning or whether the body was immersed after life was extinct. The principal diagnostic points are the external appearance of the cadaver, the presence of water in the lungs and stomach, and of froth about the nostrils and mouth, and the condition of the blood.

M. Henri Bougier, in a recent thesis (*Gazette Médicale de Paris*, May 8, 1886), presents a review of the opinions of many of the authorities in regard to these

points, as well as the results of observations made by himself.

As to the external appearance of the body, he says there is nothing characteristic. Marks of violence may, of course, exist and yet prove nothing, since the individual might have received injuries, accidentally or at the hands of others, and afterward have fallen or been thrown into the water.

Water may enter the lungs of bodies immersed after death, but in this case it is found only in the bronchi of medium size, while in the drowned it is drawn into the smallest tubes. The presence of water in the stomach, he says, is a fairly conclusive evidence of death by drowning, although, we would add, its absence would not necessarily prove the reverse, but may indicate, as Tidy remarks, a rapid death by asphyxia before the sufferer had had time to swallow.

M. Bougier regards water in the middle ear as a sign of considerable importance, having found it in twenty-one out of twenty-seven cases of death by submersion.

The froth about the mouth and nose is never found, he says, in bodies which have been immersed after life was extinct. Its presence would, therefore, point to drowning as a cause of death, but it should be remembered that if the person have been rapidly asphyxiated there might be no froth present, assuming, as is commonly supposed, that it is produced by the sufferer's struggles for breath. And, again, it will not be found if the face have been long out of the water when the examination is made.

The fluidity of the blood is one of the most striking conditions found in those who have died from submersion. This is especially noticeable, the author remarks, when the periosteum is stripped off from the cranium. The blood will be seen to ooze out from the bone in minute drops, which rapidly increase in size and soon begin to trickle down the side of the head. This fluid condition of the blood may be found in those asphyxiated by deleterious gases, or poisoned by opium or certain other narcotics, and it might then be necessary to examine the blood chemically or by the spectroscope. In those immersed post-mortem, M. Bougier always found clots in the heart and great vessels, and even in dogs killed by illuminating gas and then immersed these clots were present. It is stated, however, on the authority of Professor Brouardel, that the blood remains fluid only in the case of a slow death, and consequently, if asphyxia have been rapidly produced, clots may be found in the heart even after drowning.

The conclusion to be drawn from the investigations of the author and of others would seem to be that, in certain cases, it might positively be asserted that death did occur from drowning, but that in other cases, especially if asphyxia have been rapidly produced, all certain signs might be absent, and the diagnosis could be made only after a most careful and discriminating study of all the evidence obtainable by external and internal examination of the cadaver.

A REMARKABLE RECORD.

Mr. Lawson Tait publishes a list of one hundred and thirty-nine consecutive ovariotomies performed in 1885, without a death. This success, says Mr. Tait, is the basis of a large number of lessons. One of these is that it has absolutely destroyed our fear of the peritoneum, and "has justified our opening that sacred sac very much as we open our pockets." After ovariotomy, "on the slightest indication of peritonitis, we give a purgative and the inflammation subsides."

"The absolute want of fear of the peritoneum," he adds, "which has grown out of our success as a matter of necessity, has brought about many other startling changes. We are now dignified by the name of the 'Birmingham School of Gynecology' and our views are treated with respect; but it is not many years since language of a totally different kind was levelled against my colleague, Dr. Savage, and myself, and many blows had to be received, and not a few were given back. But the incredulity which was so freely expressed in this country by people who would not come to see for themselves, was speedily overcome by the evidence of those who came in large numbers from America, and finally by a missionary tour which I undertook in the States, demonstrating on material freely supplied to me there, and to audiences neither stupid nor prejudiced, many of the most important facts which were capable of demonstration, according to Sir Spencer Wells, only in Birmingham, and were non-existent in London or elsewhere in Europe. This attitude of Sir Spencer Wells is apparently still maintained by him; for, in a recent address delivered here, he passed by all these facts without allusion to them, 'deaf as the adder which closeth her ear.'"

As may be seen, Mr. Tait neglects no opportunity of giving Sir Spencer Wells a rap.

Another change effected by the "Birmingham School" is the adoption of short incisions, Mr. Tait's incisions only averaging two inches.

Mr. Tait still adheres to dry, absorbent cotton-wool as a dressing, quite free from any germicide. His fear of germs has steadily diminished. In the treatment of the peduncle the intra-peritoneal method is always adopted, and the silk ligature is also uniformly employed, whereas Dr. Keith uses the cautery. In cleansing the peritoneal cavity sponges have been given up, and the cavity is irrigated with blood-warm water, neither boiled nor disinfected, but "full of germs and spores."

The conclusion which Mr. Tait enunciates with the greatest apparent satisfaction is, that "all the conclusions formulated by Sir Spencer Wells in 1878 have been reversed."

The grievance must be profound which leads so distinguished and skilful a sugeon as Mr. Tait to load his invaluable contributions to surgical art with evidence of personal ill-feeling. But it is in history that our eminent surgeons have been eminent fighters.

THE MAXWELL TRIAL.

The Maxwell trial, which was recently finished in St. Louis, has brought out some points of medical interest. Maxwell's defence was that he killed Preller accidentally while administering chloroform, and the chloroform was given in order to enable him to get a catheter through a stricture. Now, as surgeons never give anæsthetics when an attempt is to be made to pass a catheter, it follows that Maxwell, if he did as he said, was an utter ignoramus. This, we believe, he admitted. But, being

totally ignorant of surgery, he yet attempts to give an anæsthetic and perform an operation! The story is a very extraordinary one.

On the other hand, it is well known that it is not an easy matter to kill a person with chloroform against the person's will, and without leaving marks of violence. The most rational explanation, so far, is that Maxwell is not entirely sound in mind. If the defence had made this claim they might have made out a better case for their client.

AN EXPLANATION BY M. PETTIT.

We find in *L'Union Médicale* of May 11th, a correction by M. Pettit of his statement concerning foreign delegates to the Washington meeting, upon which we commented in these columns under date of April 24th. He writes that, in the desire to be brief, he failed to state clearly what were the promises made by Dr. Billings concerning the expenses of those proposing to visit this country in 1887. What this gentleman really did say, he now explains, was that the fatigue of the voyage would not be great, since it would be made in the summer during the pleasant time of the year. As to the expense of the trip, he thought it would not be as heavy as his hearers expected, as he hoped that the steamship companies would consent to a considerable reduction of the ordinary rates, and that his American confrères would extend to their visitors as cordial a hospitality and as hearty a welcome as had been given to the foreign guests in Copenhagen. He adds that though Dr. Billings was careful not to make a definite promise, but simply expressed his hopes of what would be done, he spoke with so much fervor that none of his auditors doubted that his hopes would be realized. He himself at first thought that Dr. Billings spoke officially for the profession in America, but such was not the case.

We are glad that M. Pettit has so generously corrected this error, which we are sure he committed in good faith, and into which he was doubtless led through his unfamiliarity with our language when spoken. For, while every one in this country is satisfied with Dr. Billings' explanation, our brethren in France might have supposed, as, indeed, apparently they did, that the consent of the Congress to meet in Washington was obtained through misrepresentation. The scriptural injunction to "be swift to hear, slow to speak" is an excellent rule, and one that might have been advantageously followed by some others, who are not so far away from us as M. Petit, in this matter of the International Congress.

A POSTHUMOUS TEST THE ONLY ONE FOR GREATNESS.

There was a time when a man of mark, whether in letters or politics, science or art, closed his eyes serenely on the world without a misgiving but that he had done all in his power to show that henceforth he had a mortgage on its fame to be transmitted to his heirs and assignees forever. But the nineteenth century changes all this. No man will be considered truly great until he has proved it, not only by his works, but by exhibiting his brain; the calvarium must be opened, and from its casket the organ of thought must be lifted by scientific fingers, peered at through investigating glasses, searched with microscopic lens, and then if it can be shown that the one undergoing the crucial test has the third frontal convolution very much developed, and the upper part reduplicated where ordinary brains present only a wavy appearance; if the right quadrate lobe is very complicated and divided into two parts by a furrow branching off from the occipital fissure, and that of these two parts the inferior has a number of stellate branches, and the occipital lobe is small, especially in the right side, and the whole appearance is "very fine, great, and diagrammatically regular;" if a brain can show all this its owner shall be coroneted with laurel, for such was Gambetta's brain. So says the Anthropological Society in Paris; and such a brain, irrespective of previous deeds, is necessary to admit one to Walhalla.

THE LAWS OF REPRODUCTION.

It is not our intention to interfere in the correspondence in our pages on the subject of the "Determination of Sexes." We desire, however, to point out that Mr. Albert C. Beale, who wrote recently an interesting letter on the subject, appears, unfortunately, to have based his arguments on entirely false premises, which of necessity destroy the value of his conclusions.

Our correspondent claims as a law the principle that "the ovum only is necessary to reproduction," and that "the spermatozoid is not always necessary to the life of the germ."

We believe that the first proposition, so far from being a law of nature, is in fact contrary to the teachings of our most advanced naturalists, and an error.

The example given in support of this principle, in the aphis, appears to show that Mr. Beale's knowledge on the subject is rather limited. It is true, as he states, that the female aphis can propagate a whole season without the presence of the male, but his explanation is very nude of the truth. He says, "their ova not only develop into adult insects," "but, what is more uncommon, become perfect females."

These assertions are wholly unsupported by any authority; in fact, every work on the subject states that it is only in the fall of the year, when this method of reproduction has ceased, that the "true females" and "perfect insect" appear. This abnormal process of reproduction has been studied out, and is well understood at the present day as being an example of what is known as the "alternation of generation;" there are numerous forms of life in which it takes place, where at one time of life development takes place by budding, at another time by eggs. In the aphides the reproduction from the virgin insect are merely buds (not ova), and are not fertilized, and do not need it.

As Huxley says, it may appear paradoxical to speak of one million of *aphides* being parts of one morphological individual, but to a naturalist acquainted with the remarkable and similar forms of reproduction it causes no shock. In the *hydrozoa* and *medusæ* we find equally remarkable acts of reproduction, and in some forms these buds lead a free life, and in others they remain attached. In the lower forms of life we can watch the process under the microscope and experience no surprise, but

when we see the same process extended to the higher forms of life, where it is abnormal, as Huxley says, it gives a shock. Surprise, however, may be diminished when we consider that *planarians* may be violently cut in pieces, and that in eleven days each piece will become a well-formed planarian.

The explanation of the reason why parthenogenesis has survived in the case of the aphides and some kindred forms appears to be that it enables them to come into existence immediately in countless numbers, and thus insuring existence when exposed to great vicissitudes in the struggle for existence; whereas, if limited to the slow process of ovulation, the species would become extinct.

We think we have shown that the special mode of reproduction claimed by Mr. Beale in the aphides is something abnormal, especially as in this case it merely lasts for a part of the season, at the end of which the usual sexual process is called in force to continue the species. It is, therefore, no law of nature; and as to his proposition that the male element is not essential, we may remind him that in all animals above the protozoa, including the sponges, male and female reproductive elements are to be distinguished. Even in the protozoa, where no true sexual generation occurs, something very similar takes place in what is called conjugation, where two individuals coalesce and become one body.

SOLUTION OF FALSE MEMBRANES.

For many years, lime-water was the only solvent recommended for use in dissolving false membranes. During the past few years, several new remedies have appeared, and some of them seem to have positive value. Perhaps the two most notable ones are trypsin and papayotin. With the value of the former the readers of The Record are familiar, as several articles upon the subject have appeared in our columns.

It must be premised, with all these solutions, that the conditions of artificial digestion of fibrine and the solution of fibrinous pseudo-membranes are not exactly the same. In one case, the substance to be acted upon possesses no vitality of its own. In the other, it is in contact with living tissue. But therapeutics result from clinical observation, and it has been found that both trypsin and papayotin solutions do cause a disappearance of fibrinous exudations.

One difficulty in regard to trypsin has been the preparation of a permanent solution. Repeated trials of various antiseptic agents have shown the preferable one to be chloroform (pure), in the strength of about one per cent. Of course, the objection to most antiseptics is that a strength necessary to keep the solution inhibits the action of the ferment. Chloroform has been found to be free from this objection, and seems to be the ideal agent. Another important fact has been demonstrated in regard to the temperature at which these solutions should be used. It is found that at a temperature of 130°, the action is speedier and more efficient.

In the *American Journal of Pharmacy*, November, 1885, Martin gives the results of his experiments with papayotin, a proteid derived from papaw juice (carica papaya). He found it soluble in distilled water, and precipitated by nitric acid. It differed from a native albumin, however, in not being thrown down by heat. The results of Martin's experiments in the artificial digestion of milk were convincing as to the actual digestive power of the new agent. He found that its action was much slower than that of trypsin, and that it did not result in a true peptone. Of course, this latter point is non-important so far as the solutions of false membranes is concerned.

Many physicians have made trial of trypsin in diphtheria, and the verdict is quite general in its favor. The use of papayotin has been by no means so general. First recommended, we believe, by Rossbach, it was afterward regarded by him as very uncertain, on account of the variability in preparations on the market. This objection has been removed by greater care by the manufacturers. Merck's preparation is now considered reliable. It is over five times as expensive, at present market rates, as trypsin.

With both the above-named solvents, an alkaline reaction favors activity. Of course, the mere removal of inflammation exudations is but a part of the problem. On the theory of the local nature of diphtheria, with subsequent constitutional infection, their removal is a matter of necessity. Treatment with reference to this end must be begun early. The use of these solutions seems to promise good results. They are, however, at the best, only adjuvants. The terrible depression of the disease must, from the outset, be counteracted.

News of the Week.

Pennsylvania State Medical Society.—We learn from our despatches that there is considerable excitement over the fact that the Philadelphia delegation to this society has not been allowed to register, and that the matter has been referred to the council. Up to the time of going to press no decision has been rendered.

Transplantation of the Tendon of a Dog to Man.—M. Peyrot, at the meeting of the Paris Société de Chirurgie, May 5th, reported a case in which retraction made it impossible to suture the divided ends of the medius. He removed a piece of tendon from a living dog and sewed it to the divided tendon. The result was successful functionally as well as anatomically.

Seventeenth Annual Report of the New York Physicians' Mutual Aid Association.—The benevolent work of this association continues to prosper. The permanent fund, which was already nearly eleven thousand dollars, received an increase of over one thousand dollars during the year. Disbursements were made to the families of ten physicians who died during the year. Money was also loaned to a sick member out of the permanent fund. The officers are working hard to increase the society's membership and widen its field of usefulness. In this they deserve a hearty co-operation from the profession.

The Lowest Temperature on Record.—Dr. C. W. Suckling reports in the *Lancet* the case of a woman dying from myxœdema, whose temperature the day before ranged from 66° F. to 76° F. The pulse was 36: respirations, 12.

The Woman's Medical College of the New York Infirmary held its annual commencement on May 29th, when a class of eight was graduated.

Dr. Dyce Duckworth took a trowel to the Queen and received knighthood in exchange. The trowel was the one used by the Queen in laying the corner-stone of the Royal College of Physicians and Surgeons.

Our Learned and Scholarly Contemporary, the *Medical and Surgical Reporter*, is a stalwart supporter of the Old Code. This is an excellent thing, and is another reason for admiring the sun-set covers of our neighbor. We believe, ourselves, in all that is moral in the Old Code, and especially in the section which says, "it is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them." Yet we observe, with sorrow, that there regularly appears in the daily papers an advertisement of a certain proprietary "water," which is "the famous specific for the cure of Bright's disease," and is endorsed by D. G. Brinton, M.D., of Philadelphia. We beg our erring contemporary to set a better example.

Pasteur Defends Himself.—In reply to my remark that the drift of opinion in America seemed to be that it is necessary to wait for proofs of protection in those already inoculated, he said with great energy: "Wait? I have no objection. *I* am waiting. But consider this: In October last I began systematically to inoculate human beings. Up to this moment (April 29th) we have inoculated 907 persons. How many deaths? One. One only (for the Russians cannot justly be counted), and when this one (the Pelletier child) came to me it was too late. Before I began to inoculate human beings, how many of those bitten by mad dogs in France died? Sixteen per cent. Since last October only one death in 907 cases! What more can you ask? Scientific men once doubted my having discovered a means of preventing cholera in chickens and charbon in sheep. When I announced my discovery at the International Medical Congress in London, Koch said, 'Pooh!' and Chauveau simply loaded me with sceptical objections. Do they do it now? Let the fact that 500,000 sheep are inoculated every year in France for peasants who fight to save a two-sous piece and yet must pay four sous per head for inoculation every spring, be the answer. The Germans are angry, especially Koch, because France has the merit of this new discovery of protection against rabies. They think because they conquered our country in 1870 that they can be our masters in this field, and therefore they spread broadcast their scepticism against me. They lack generosity. They are behaving like children."—*Cin. Lancet, Med. and Surg. Journ.*

Importing Foreign Surgical Talent.—Boston was obliged to experience the mortification last year of having a British gynecologist, Dr. Keith, called all the way from Scotland to give his advice. Now it may feel satisfaction in learning that a Berlin surgeon has been summoned to London to perform a thyroidectomy on a celebrated barrister there.

The Accouchement of a Turkish Princess.—Dr. J. A. S. Grant, of Cairo, Egypt, writes to the *Albany Medical Annals* that he was recently summoned to conduct the accouchement of a Turkish princess. The lady in question had heard of chloroform and wanted it given, hence the violation of the ancient custom. Dr. Grant gave her the chloroform when the pains came on. Between the pains the patient smoked cigarettes. Before the event was over her husband brought in a Turkish doctor, in order that he might learn how to give the anæsthetic. Everything went off well, and there is great probability that European methods will begin to prevail in the conduct of accouchements in the harem.

Lady Medicals and the Philadelphia County Medical Society.—The appearance of the names of several women practitioners on the list of propositions for membership in the Philadelphia County Medical Society indicates that the struggle which formed so prominent a feature in the Society two years ago is to be resumed. It will, perhaps, be impossible to predict the outcome of this second attack.

A Prurient Medical Journal on Religion.—A weekly Parisian journal, the *Journal de Médecine*, has been criticising "the Yankees." The journal in question supports a "feuilleton" made up of stories and poems so-called which are generally obscene and rarely witty, and which are published under the head of "Anecdotes Médicales," etc. Of late the *Journal* has regaled its subscribers with a translation of the *Pall Mall Gazette* exposures, which have formed a kind of under-current of sewage for several weeks. Naturally the *Journal* is astonished to read an article in The Medical Record entitled "The Doctor and Religion," and having translated it we are taken to task for bolstering up hypocrisy and advocating "a religion of the toilet." Our editorial was a plea for the qualities of reverence and faith, and what it had to do with the toilet is hard to see. At any rate we feel that we need not explain, and least of all justify, our remarks. We certainly do not ask our contemporary to be religious; indeed, if he will only be clean and decent it will be a great gain. At present his faith seems mostly pinned on prurient literature and medical doggerel. Our contemporary by and by may be fitted for religion; at present he needs education.

The Weekly Medical Review heads its department of "Notes and Items" with

> "A chiel's amang you takin' notes,
> And, faith, he'll prent 'em."

Our usually alert contemporary was nodding when it printed the above lines, and for the credit of the present geographical and future medical centre of the country we trust they will be corrected.

The Western Pennsylvania Medical College is the title of the new medical college which begins work in Pittsburg next October.

Consumption from the Milk of City Cows.—The Paris Council of Health has reported in favor of the expulsion of dairy cows from Paris. There are upward of five thousand of these animals in the capital, and they are claimed to be a prolific source of pulmonary consumption. It is even said that the milk of a great number of them was alive with the bacillus tuberculosis. Many of these animals have been subjected to in-and-in-breeeding, thus intensifying predisposition.

The Skin and Cancer Hospital.—The "Kirmess" held for the benefit of this charity last week netted between five and eight thousand dollars. The kirmess was held out of doors, and was very picturesque. There was a great deal of fashion, if not of beauty, in attendance.

Dr. R. W. Pease, a surgeon who was prominent in the medical department of the army during the war, died suddenly at Syracuse from heart disease on May 28th.

The Long Island College Hospital held its annual commencement on June 2d, and graduated forty-nine students.

The New Hampshire State Medical Society will hold its ninety-sixth annual meeting at Concord on June 15th.

The Pasteur Institute.—The Chamber of Deputies has voted 100,000 francs to the fund for the establishment of the Pasteur Institute.

The Nebraska State Medical Society held its eighteenth annual session at Lincoln, June 1, 2, and 3, 1886.

The Ninety-fifth Annual Meeting of the Connecticut Medical Society was held at New Haven on May 26 and 27, 1886, with the President, Dr. E. C. Kinney, in the chair. The opening address of the President was followed by the report of the Treasurer, Dr. E. P. Swasey, which showed a balance on hand of $501.02. The following officers were elected for the year ensuing: President, T. M. Hill, M.D., of Willimantic; Vice-President, Francis Bacon, M.D., of New Haven; Secretary, S. B. St. John, M.D., of Hartford; Treasurer, E. P. Swasey, M.D., of New Britain. The President's address was a history and study of "Diabetes Mellitus" from the time of the first discovery of sugar in the urine to the present time.

He arrived at the conclusion that the disease appeared to be on the increase, and that it was particularly affecting our profession. He urged that operations on diabetic patients were dangerous.

Dr. W. H. Carmalt related the case of a woman who had a cataract, on whom he did not dare to operate while she had diabetes mellitus, but when the symptoms had disappeared he did so. She never recovered from the shock, and there was no effort on the part of nature toward repair, and she finally died on the fourth day.

Dr. A. W. Nelson, of New London, related four cases of diabetes mellitus that he had had under his care. One case was that of a man who had both albumen and sugar in his urine, but was comfortable at present, under treatment by opium and arsenic.

Dr. A. T. Douglas thought if any operation was to be performed where there was diabetes mellitus, that it should be early in the disease.

A paper on the microscope in its relation to disease was presented by Dr. J. W. Wright.

Dr. J. G. Stanton had prepared a paper with the title "O Tempora! O Mores!" The points of his paper were that qualified physicians should demand from the Legislature laws protecting the people from the numerous quacks that infest this State and deceive the public with the assumed name of "doctor."

In accordance with a motion made by Dr. Carrington, that a committee of three be appointed by the chair to confer with the Homœopathic and Eclectic Societies in reference to the adoption of an act substantially like that recommended by the American Medical Association, Drs. Carrington, Wainwright, and White were appointed.

Dr. W. S. Munger read a paper on morbus Brightii, and Dr. S. D. Gilbert one on pneumonia.

These papers were interesting and practical, but advanced no new ideas.

Dr. F. E. Beckwith read a paper entitled "The Treatment of Laceration of the Cervix Uteri," and gave the history of twenty-six original cases of trachelorrhaphy. He thought that in all cases of parturition the woman should be examined in about six weeks after delivery, and if any eversion or erosion was found resulting from a laceration of the cervix uteri, that trachelorrhaphy should be performed.

Dr. P. H. Ingalls did not think an operation should be performed when there was any cellulitis.

Dr. F. H. Whittemore remarked that in many cases bad symptoms were not developed until several years after parturition.

Dr. Constantine J. MacGuire has been appointed Visiting Physician to St. Vincent's and Charity Hospitals, New York.

Resignation of Professor L. M. Bingham.—The Trustees of the University of Vermont unanimously adopted the following resolutions with reference to the recent trouble in Burlington:

"*Resolved*, That while this board of trustees recognizes the right of students in any of the departments of the University to ask their attention to any well-founded grievance, they regard the petition of the medical students to the medical faculty, which has been by that faculty laid before the trustees, in effect demanding the resignation of Dr. Bingham as professor of surgery, as so dictatorial and offensive in manner, and the conduct of the said students in refusing to attend lectures as being so like lawlessness and violence, that this board cannot properly consider the same.

"*Resolved*, That the trustees express their confidence in the capacity and qualifications of Professor Bingham for the duties of the chair of surgery in the medical department of this University."

In view of this vote of confidence on the part of the trustees Dr. Bingham tendered his resignation, which was accepted.

A President of the American Medical Association Advising a "Boycott."—The late President of the American Medical Association, Dr. Wm. Brodie, in his annual address, accused the *New York Medical Journal* and the *American Practitioner and News* with having antagonized the Association, and said that these journals had better change their editors "if they wished to retain the patronage of the members of the Association." This is nothing more nor less than a threatened "boycott," and it was warmly resented in a letter written by Dr. D. T. Smith to the *Weekly Medical Review*. Dr. Smith says: "I had cherished the pleasant delusion that the members of the American Medical Association, as indeed all progressive physicians everywhere, selected their professional journals with a view to the thoroughness, freshness, and high character of their

contents, and the literary excellence of their style, and not because they might be found trimming to every passing breeze of opinion. Notwithstanding the baselessness of the charge referred to, and the question that urgently suggests itself, as to the propriety and dignity of going out of the way to introduce personalities into an address from the exalted position of President of the American Medical Association, intended for the vast audience of American physicians, any disapproval of the *Practitioner and News* should have been left to be expressed through its columns. But when the great powers incident to the high office are utilized in suggesting a boycott on account of a respectful difference of opinion, I should feel that I had done less than my duty if I should fail to enter a respectful protest. In the present sad juncture of affairs there are quarters where suggestions or propositions of boycotting would not occasion surprise; but I feel doubly safe in saying that the membership of the American Medical Association cannot fail to regard a suggestion, from any source, for it to join in a boycotting enterprise as not respectful to its sense of honor, and inconsistent with the dignity of its high character, and not to be for one moment entertained." We cannot believe that Dr. Brodie meant all that his words implied, but his expression was certainly unwise and injudicious.

Reviews and Notices.

LOCAL ANÆSTHESIA IN GENERAL MEDICINE AND SURGERY. Being the Practical Application of the Author's Recent Discoveries. By J. LEONARD CORNING, M.D., formerly Resident Assistant Physician to the Hudson River State Hospital for the Insane; Member of the Medical Society of the County of New York; Fellow of the New York Academy of Medicine, etc. New York: D. Appleton & Co. 1886.

IN this brochure the author describes his method of producing local anæsthesia by means of hypodermic injections of cocaine combined with arrest of the circulation in the part, and demonstrates its applicability to many of the larger operations. A considerable portion of the monograph has already appeared, in papers, in THE MEDICAL RECORD and *The New York Medical Journal*. It is an interesting and instructive work. Numerous illustrations serve to elucidate the text.

VON ZIEMSSEN'S HANDBOOK OF GENERAL THERAPEUTICS. In seven volumes. Volume I.: Introduction; The Dietary of the Sick; The Koumiss Cure. Volume II.: Antipyretic and Antiphlogistic Methods of Treatment; Epidermic, Endermic, and Hypodermic Administration of Medicines. Volume III.: Respiratory Therapeutics. New York: Wm. Wood & Co. 1885.

THE great success achieved by the series of volumes known as Ziemssen's "Cyclopædia" has quite naturally led to the present undertaking. It aims to give a full account of the entire subject of general therapeutics. The text is supplied from the pens of the most eminent German authorities in the various departments of medical practice. A work of this magnitude (seven octavo volumes), dealing with so many subjects of universal interest to the profession, has not hitherto been essayed in any country. It is a matter of congratulation for English readers that the several treatises comprising the entire series are made accessible to them so soon after their appearance in the original. This is clearly an instance in which the publishers deserve unstinted praise for the quick appreciation of what would prove most acceptable to a large contingent of the entire profession.

Having said so much in a general way, it must suffice to indicate the special nature of this handbook by a cursory glance at the contents of the three volumes that are already before us.

In the first of the series Professor Bauer deals in a thorough and comprehensive manner with the highly important subject of dietetics. An excellent account is given of the general dietary of the sick, and this is supplemented by an adequate description of dietetic methods of treatment, such as grape, milk, and whey cures. In an appendix Dr. Stange discusses the various koumiss cures in all their practical bearings on diseased states.

The second volume begins with antipyretic methods of treatment, which are fully and ably explained by Professor Liebermeister. Dr. Jürgensen takes up the discussion of antiphlogistics, blood-letting, and transfusion, while to Eulenburg have been assigned the subjects of epidermic, endermic, and hypodermic medication. These three authors are well known to the profession of both hemispheres, and their articles are complete, reliable, and fully abreast of modern views concerning the subjects dealt with. It is deserving of notice, also, that the translation has been so well done that there are no unpleasant hitches in the reading of these monographs.

Volume III. largely exceeds in bulk the first two of the series, numbering no less than 768 pages, which are entirely devoted to the intricate subject of respiratory therapeutics. The author is Professor Oertel, of Munich, and as the translator, Dr. Yeo, has well expressed it, a conspicuous merit of the German savant's work lies in the fact that he endeavors to supply "a rational and scientific as well as an empirical basis for all the methods he recommends."

If the high standard of excellence achieved by the volumes hitherto issued is maintained, the eminent success of the "Handbook of General Therapeutics" is assured.

GUIDE TO THE EXAMINATION OF URINE, with Special Reference to the Diseases of the Urinary Apparatus. By K. B. HOFFMAN, Professor at the University of Graz, and R. ULTZMANN, Docent at the University of Vienna. Second Edition. Translated and Edited by F. FORCHHEIMER, M.D., Professor of Physiology at the Medical College of Ohio, Cincinnati. With Illustrations. Cincinnati: Woodruff, Cox & Co. 1886.

THIS is a very practical and useful little work, which everyone called upon to make urinary examinations will find of great service. The authors go most thoroughly into the subject, much more fully, indeed, than most writers of similar guides, but the mass of instruction contained in the book is made readily accessible by means of the excellent index compiled by the translator. The value of the American edition is enhanced by numerous fairly well executed illustrations.

CONTRIBUTIONS TO THE TOPOGRAPHICAL AND SECTIONAL ANATOMY OF THE FEMALE PELVIS. By D. BERRY HART, M.D., F.R.C.P.E., Lecturer on Midwifery and Diseases of Women, School of Medicine, Edinburgh, etc. Edinburgh and London: W. & A. K. Johnston. 1885.

DR. BERRY HART deserves great credit for the industry with which he has devoted himself to the task of elucidating some of the obscure points connected with the normal and pathological relations of the female pelvis. The present work consists of twelve beautifully executed plates, drawn from frozen sections of well-formed cadavers. All those interested in the anatomy of the female human pelvis will welcome this collection of faithful representations of undistorted parts. The brief text accompanying the plates is explanatory rather than controversial, although a number of mooted points are brought up by Dr. Hart, and treated in a spirit of fair criticism.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 28, 1886.

JOHN A. WYETH, M.D., PRESIDENT, IN THE CHAIR.

PREGNANCY COMPLICATED WITH UTERINE FIBROID—RETENTION OF URINE AND PYO-NEPHROSIS.

DR. C. C. LEE presented a specimen, removed from a married woman, thirty-seven years of age, who was admitted to his service in the Woman's Hospital on March 16th, with the following history: She had been married two years, had never borne children, but had had a miscarriage eight months previous to her admission, at about the second month of utero-gestation; the cause of the miscarriage was not known. When admitted she had been ill for two months, complaining chiefly of retention of urine, with great dysuria, œdema of the lower extremities, and slight shortness of breath. It was supposed by her physician that she had an ovarian tumor. On examination it was found that she was pregnant, and had the following peculiar condition of the bladder: this organ was drawn up under the abdominal walls above the umbilicus, and was enormously distended with urine. On passing the catheter, between eighty and ninety ounces of urine were withdrawn, and the tumor subsided. After this had been done it was very easy to recognize the presence of uterine fibroids. The pregnancy was estimated to be between the third and fourth month. The uterus was displaced backward into the cavity of the sacrum, and the retroversion was so fixed that all efforts to replace the uterus were ineffectual. The fibroids were three in number, and their outlines could be distinctly made out. It was quite evident that the retention of urine had been due to the rapidly increasing size of the fibroids, and that one of them had pushed the lower third of the bladder against the pubis in such a way as to partially close the exit for the urine. When the urine was examined it was found to be alkaline, with a specific gravity of 1,012, slightly purulent, quite albuminous, and after the lapse of a few days it exhibited hyaline casts. The diagnosis was pregnancy, complicated with fibromata, which had produced retention of urine by pressure on the lower part of the bladder, and probably secondary pyo-nephrosis. The cervix, however, had been crowded up so far that it was almost impossible to reach it, and was above the arch of the pubis, so that the question of the induction of premature labor was decided in the negative. The patient developed pneumonia on the tenth day after admission, and died with high temperature and the symptoms resulting from that disease. Whether the pneumonia was due to septicæmia or some casual reason was not easy to determine, and it was believed to be possible that the patient lost her life because premature labor was not induced. Miscarriage did not occur.

At the autopsy the lower and middle lobes of the right lung were found in a condition of partial resolution, with a large quantity of serum in the pleural cavity of that side. The heart was flabby, but not otherwise diseased. In the abdomen the three fibroids presented themselves with the bladder drawn up over them to a great extent, and the largest of the three had caught the lower portion of the bladder against the pubis; the fibromatous mass had also pressed the uterus into the cavity of the sacrum, thus giving an additional reason for the immovable retroversion. The uterus contained the fœtus, and presented no peculiarities. The ureters were dilated, slightly inflamed, and both kidneys had undergone extensive and rapid degeneration, so that only a small amount of kidney-tissue remained. The pyo-nephrosis was evidently of rapid development, and due to the retention of urine caused by pressure upon the lower portion of the bladder by the fibroids.

Dr. Lee thought it was probably an error that premature labor was not in some way produced, although the condition of the parts was such as to render it almost impossible.

HEGAR'S OPERATION.

Dr. Lee also presented the ovaries and tubes removed by Hegar's operation, for the relief of an intractable submucous uterine fibroid, sessile in character, and occupying the entire fundus of the organ. The patient was a young woman who, besides the loss of blood which the fibroid had caused, had suffered terrible pain, and had had two or three attacks of pelvic peritonitis. After due consideration it was decided to force the menopause by removal of the ovaries, and Dr. Lee was influenced somewhat in making this decision by the fact that he had already reported two cases where he had attempted to remove the fibroid by means of the serrated spoon, and with disastrous results, and also the fact that the patient had been ineffectually treated by injections of ergot. Dr. Lee found it exceedingly difficult in this case to remove the tubes and ovaries, on account of the very extensive adhesions. The patient, however, had done well, and was convalescent, the operation having been performed about ten days ago.

EXPLORATIVE LAPAROTOMY—DOUBLE PAPILLOMA OF THE OVARIES.

Dr. Lee, on Saturday last, had occasion to perform explorative laparotomy in a case which was supposed to be one of multiple uterine fibromata. The patient was twenty-seven years of age, single, and for two years had been suffering constant pelvic pain, which was increased with menstruation. A pelvic tumor had been recognized by two consulting physicians. At the first examination Dr. Lee concurred in this opinion, but on account of the severity of the pelvic pain he afterward concluded that it would be best to give the patient the advantage of the explorative incision. When he had opened the abdomen, he found that there had been a mistake in diagnosis by himself and the other physicians, and that there was a double ovarian tumor. The error in diagnosis was apparently due to the fact that the sac was of unusual thickness, and gave no distinct sense of fluctuation, but rather an elastic feel which resembled fluctuation, and was regarded as indicative of a soft fibromata. The peculiar feel was such that Dr. Lee thought it was altogether probable he would be likely to make the same mistake again. He exhibited the specimen for the purpose of enforcing the view that where the surgeon was in doubt in such cases, the explorative incision was the proper procedure to be adopted. He had not seen any fatal results from the operation, and it enabled the surgeon to be sure of the nature of the trouble within the abdomen. The uterus in this case was normal, but there was a double ovarian tumor of a true papillomatous character, the inner surface showing distinctly the papillomatous growth, and each cyst was filled with a thick and gelatinous fluid. At the present date, five days after the operation, the patient was doing well.

DR. BOLDT asked how long the retention of urine lasted in Dr. Lee's first case.

DR. LEE said that the retention was not at any time complete, but that it lasted for a month previous to admission, and the patient was in the hospital a month.

DR. BOLDT remarked that retention with retroversion was very likely to be accompanied by cystitis, and in the cases reported it had always been in such a degree as to be serious, the cystitis being primary and the condition of the kidney secondary, and all the cases had terminated fatally if the displacement could not be reduced.

DR. WALDSTEIN asked Dr. Lee if it was not possible that in his second case the menopause might not be established, as had been observed by Hegar himself, so that the result of the operation might be negative.

DR. LEE said it was quite possible that this might oc-

cur, but such a result was probably a rare exception and not the rule. Often, however, where the menopause does not occur, the flux of blood which the uterus receives is much lessened by the operation, provided such an amount of peritonitis is not produced as to obstruct the pelvic circulation.

Dr. Waldstein said that he simply put the question because the operation seemed to him to be a severe one for the patient who gave the symptoms of fibroid of the uterus. The condition of the ovaries seemed to be the result of the examination made at the laparotomy.

Dr. Lee said the condition of the ovaries was only recognized after the explorative incision had been made, but the fibroid was of such a character that it could not be removed by the more usual methods.

Dr. George F. Shrady presented a specimen which he had received from Dr. Hays, of North Carolina, who removed it at autopsy from the body of a white man of middle age who died of typhoid fever in Charleston Hospital in 1883. It was a part of the outer surface of the spleen removed from near the hilus, and consisted of either ossific or calcareous matter, and in order that its exact nature might be determined it was referred to the Committee on Microscopy. [The Committee reported subsequently that the substance was calcified connective tissue, resulting from chronic perisplenitis.]

FREE BODIES WITHIN THE SAC OF A HYDROCELE.

Dr. Waldstein presented a specimen which Dr. Lange had given him for examination. The case was one of varicocele occurring in a patient twenty-one years of age. After excising the same Dr. Lange found that there was a small hydrocele, which he incised and removed from the sac small free bodies which, on examination, proved to be of a fibrous character with calcification. Dr. Waldstein had examined the literature of the subject somewhat, and had found that Virchow had mentioned these bodies as originating in a pure orchitis proliferans, and that excrescences, fibrous in nature, generally from the albuginea, became calcified and were freed, and then were found loose in the sac. Sometimes they also originated from the hydatid of Morgagni, but such was not the origin of the specimens presented.

ANGIOMA CAVERNOSA.

Dr. Waldstein also presented a specimen removed from the outer side of the left leg of a girl five years of age. It was located very near the outer condyle; it was painful, and so impeded the action of the leg, and affected the flexion of the knee-joint that her gait was from the hip. The question arose whether or not the tumor could be removed. During the last two and a half years it had not perceptibly grown. Dr. H. B. Sands performed the operation, which was entirely successful. It could not be determined positively whether the tumor was connected with the articulation, or was within the skin, or was subcutaneous, or was adherent to the bone, or within the muscle. Dr. Waldstein was inclined to the opinion that it was situated within the muscle, and in this view he was sustained by Dr. Sands. On making an incision over the growth it was found that the skin and subcutaneous tissue were not involved. Dr. Sands then cut into the muscle and found within the belly of it a tumor which was enveloped by a fibrous capsule, and from which it could be easily enucleated, except at the lower extremity at the termination of the muscle, where it was so firmly attached that it was necessary to cut it away with the knife. The muscular tissue in the neighborhood of the growth had visibly degenerated, and on section through the tumor it was found that it contained some adipose tissue, but a great deal of blood. On microscopical examination it was found to be a specimen of angioma cavernosa; that is, containing a large number of newly formed and forming blood-vessels with caverna filled with blood.

Dr. Waldstein presented the specimen because of the locality in which it was found. It was an intra-muscular angioma cavernosa, and he had been unable to find any record of a similar case.

The President said that he had a specimen almost identical in history and location with the one presented by Dr. Waldstein, but which was removed from the vastus internus muscle. The patient came into his service, and it was noticed that there had been an incision made over the tumor. While he was operating a physician present remarked that there was a scar over the tumor when the operation was commenced, and he said that he saw the same patient under an operation, and the hæmorrhage was so frightful that the operator ceased at once and closed the wound. Dr. Wyeth operated by the aid of an Esmarch bandage, and no hæmorrhage whatever occurred.

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 20, 1886.

Abraham Jacobi, M.D., President, in the Chair.

Dr. C. R. Agnew read a report from the Board of Trustees, including a memorandum from the executors of the late Dr. Edward L. Beadle, stating that the Academy would, in a few days, come into possession of the five thousand dollars left it by the provisions of his will.

The President said this was the second bequest which the Academy had received within a short time, the other being the library of the late Dr. Austin Flint. The Academy was thankful for these gifts; they helped toward making it the centre of scientific labor of the profession at large, which it was destined to become. There were good reasons to believe that further donations would soon be received.

MEMORIAL REMARKS ON GASPAR GRISWOLD, M.D., M.R.C.S.

Dr. E. G. Janeway spoke of Dr. Griswold as an earnest, faithful, hopeful physician and student. He was a clear writer and a good speaker; he was able to present his thoughts in a manner to charm his audience, and as he had entered upon the labors of a medical teacher he gave promise of an exceptionably successful career.

THE DIAGNOSIS OF DISEASES OF THE HEART.

Dr. Janeway then read a paper on the above subject. It was not intended to be exhaustive; he wished simply to present certain exceptional points, in the diagnosis of cardiac disease, which had come under his observation. He would not speak of the sphygmograph.

First, with regard to the position of the heart. There were different causes for altered position of this organ which might cause difficulty in diagnosis, but the majority were sufficiently well known. There was one cause of which he would speak from clinical and cadaveric examination, namely, a lowered position of the heart and of the apex beat, owing to a long first portion of the arch of the aorta.

The pushing forward and upward of the heart in spinal curvature he had known in several instances to lead to a belief in the existence of an aneurism.

The nipple was often taken as a guide to the position of the apex of the heart in man. The examination of a large number of persons had led him to believe that this was an uncertain landmark; the intercostal spaces and the centre of the sternum were much more reliable points.

Inspection and palpation could often be relied upon to a considerable extent as affording points for diagnosis, but the writer had often been struck with the absence of perceptible cardiac impulse in hospital inmates, and also in persons in presumable good health. Sometimes, also, the cardiac impulse was not evident on palpation. This

could not be taken as indicating more than a slight lack of force in action.

Some physicians were inclined to attribute the cardiac thrill to a single condition, but Dr. Janeway thought the conditions under which it was present were variable. It was generally true that the thrill accompanying aortic and pulmonary obstruction was perceptible at the base of the heart over the respective arteries—that of the pulmonary on the left, of the aorta on the right of the sternum, but by this sign alone one would not be justified in making a diagnosis. It was true that the time of the thrill would help somewhat, but to exclude an aneurism would sometimes require a very careful examination. He had not infrequently been able to predict mitral stenosis simply by palpation over the heart, and find his prediction confirmed not only by further physical examination but by autopsy.

Mapping out the area of the heart was, as a rule, not difficult; but Dr. Janeway had been much struck by the devices which some physicians had thought it necessary to resort to to do this. A simple means would enable one to use the ordinary Cammann stethoscope, namely, let the patient hold the stethoscope to his chest-wall, which would leave the examiner's hands free for auscultatory percussion.

Students were apt to condemn a heart over which a murmur was heard, and to consider a heart normal over which no murmur was audible; he had also known of some expert examiners being misled in the same direction. They were most likely to pronounce a heart normal over which no murmur was heard. Before pronouncing a heart normal it was important not only to consider the nature of the heart-sounds, but also what effect the cause producing the murmur was having upon the heart. A difference of opinion was likely to arise, when a murmur existed over the cardiac area, as to its exact significance. There were other sources for murmurs heard over or near the heart which were of decided importance to the patient, so far as diagnosis was concerned, such as respiratory murmurs, etc.

To distinguish between the murmurs produced in the aorta and at the aortic valves was not always easy. Sometimes an aneurism, a projecting thrombus on the aortic valves, a chronic endarteritis would be found to produce either a systolic, a diastolic, or a presystolic murmur; or there might be a conjoint cause in the aorta and the valves for the murmur. The murmur of aortic regurgitation might be propagated to the apex, and if the leakage was free it might be mistaken for a presystolic, mitral, or a mitral regurgitant murmur.

With reference to mitral stenosis, in the majority of cases, when the valves were capable of vibrating, there existed a characteristic presystolic murmur, but from this decided indication of this form of disease there were divergences which might progress to that point where altogether, or at times, no typical murmur existed. The author further spoke of the difficulty which sometimes existed of diagnosticating tricuspid regurgitation, owing to the presence of a mitral systolic murmur or other conditions. The loudness or softness of murmurs was not, as was generally well known, an index of the amount or gravity of the disease inducing the murmur. A thrombus at the apex of the left ventricle, or in the left auricle, might exist without a murmur, and it might be of considerable size. So also a small, bead-like vegetation might be present on the auricular aspect of the mitral valve without a murmur. The presence of a tendinous cord in the left ventricle was not rare, and he related one case in which it was the only apparent cause of a murmur during the patient's life. The author also spoke of the significance of exceptional signs in certain cases, with pulsation of the liver, fatty degeneration of the heart, acute cardiac dilatation, ulcerative endocarditis, malignant growths, and syphilis.

Dr. E. D. Hudson, Jr., thought the profession would derive great benefit from Dr. Janeway's paper, especially as no one in this country had had a better opportunity for observing a large number of cases of cardiac disease, and of following them up by an autopsy. He would not attempt to take up all the different points brought out in the paper. With regard to the location of the apex, in health it was usually under the fifth or sixth interspace or intervening rib. If it were not found in this locality, the presumption was in favor of dilatation or hypertrophy. But an altered position of the heart might exist, which would be followed by a change in the line of conduction of a cardiac murmur if one existed. For instance, a student found a murmur conducted from the base downward in the usual line in which pulmonary regurgitant murmurs were conducted, and he made a diagnosis accordingly. Dr. Hudson called his attention to the fact that, judging from the relative number of cases of the two forms of murmur, the presumption would be altogether in favor of an aortic regurgitant, and on examination he found such to be the true nature of the case, the change in position bringing the line of conduction of the murmur in correspondence with that of pulmonary regurgitation.

In forming a conclusion as to the importance of mitral murmurs, both systolic and presystolic, Dr. Hudson thought it very important to consider the composite nature of the first sound of the heart. He recognized the fact that in many instances we could make an immediate and final diagnosis of a murmur at the apex, and determine at once whether it was a mitral regurgitant or a murmur due to mitral stenosis. But he had so often found a murmur which possessed all the characteristics of an organic murmur at the mitral valve, and at a subsequent examination found it absent, that he thought it wise if the physician postponed a final diagnosis to a future examination. At one time, owing to the influence of prominent teachers, he did not believe in the so-called presystolic murmur, but he had long since become converted to the fact of its existence. He was, however, very sceptical as to the frequency of the mitral presystolic murmur. Believing in the composite nature of the first sound of the heart, he was convinced that a great many murmurs simulated the true mitral systolic, and it would often be found that rest and measures for restoring the general health would cause their disappearance. He had come to regard as fallacious the teaching of so many authors that the transmission of the systolic mitral murmur took place through the solid structures around to the back; he thought it took place through the auriculo-ventricular opening and posterior wall of the auricle, and thence to the back.

Dr. H. N. Heineman regarded the paper as a valuable one, especially for reference in cases of cardiac disease presenting unusual symptoms and in which the diagnosis was difficult. It was important, before arriving at a diagnosis of any given case of supposed heart trouble, to take into consideration not any one sign alone, but all that might be present; we should consider the apex-beat, the size of the heart, the murmur, the impulse in the neck, the pulse, the clinical history. With regard to thrill, he had found, after observation of many cases, that it bore no relation at all to the intensity of the murmur.

Mitral stenosis was sometimes accompanied by a thrill, but this was not to be relied upon as a diagnostic sign. It might be associated with aortic stenosis, and in some cases be carried to the apex. In the latter event one would not be able to say whether it was connected with aortic stenosis or mitral insufficiency. Thrill was an uncertain element in diagnosis. If all the other elements pointed to a particular diagnosis thrill might help some. Given, a loud murmur at the aortic orifice and one at the mitral orifice, and you were satisfied that there was a lesion at both of these orifices, it would be impossible to say at the first examination whether two or three murmurs were present. Again, if there were three murmurs, two at the aortic orifice and one at the mitral, or the reverse, he maintained that it would be impossible at the

first examination to say what was the condition of the mitral orifice and what that of the aortic. Again, there might be a loud, prolonged mitral regurgitant murmur, and the examiner would be unable at the patient's first visit to say whether there was mitral insufficiency alone, or whether there was not also some degree of mitral stenosis.

Dr. A. L. Loomis had been greatly interested in the clinical and pathological experience which Dr. Janeway had related. He had given his experience upon certain points which one who studied cardiac diseases carefully would often find it difficult to decide upon. The author of the paper had first directed attention to cardiac displacement, and had spoken of a displacement due to an elongation of the aorta. Dr. Loomis once had occasion to examine a large number of healthy persons, and he came to the conclusion then that the region of the apex-beat varied in different persons more than was generally supposed. Displacement below the so-called normal point of apex-beat was most common. If now he should find the apex below its normal limit, there being the normal area of diffusion and intensity, etc., he would not for a moment suppose that it indicated cardiac disease.

The author had also called our attention to cases of feeble apex-beat in persons who had occupied the recumbent position for a considerable time. When Dr. Loomis had found this condition he had questioned in his mind whether there had not been some interference with cardiac nutrition. One who had studied cardiac diseases soon came to the conclusion that it was not the murmurs nor the changes in position of the heart which were of so much importance, but rather the integrity of the cardiac walls and of the cardiac rhythm. A mitral regurgitant murmur, for instance, might exist for years, and be a matter of little importance. But when in connection with this murmur, or any other cardiac murmur, there came a change in the walls of the heart permitting, under high blood-pressure, of a change in the cardiac rhythm, it was a matter of much significance.

With regard to thrill, that, connected with mitral obstruction, was familiar to all, for it was almost always present. But, as Dr. Janeway had said, it was by no means the only thrill. He had come to believe that the thrill heard over the base of the heart, or at the apex, was due as much to dilatation of the auricular cavity, on the one hand, or of the ventricular cavity, on the other, combined with a general condition of anæmia, as to valvular changes. And it was important to notice whether, if there were a distinct thrill and no cardiac murmurs, there was a trembling impulse, though it might be only slight.

The differential diagnosis between a presystolic mitral murmur and an aortic regurgitant was an old question. When he commenced to study cardiac diseases under Dr. Cammann, he was taught that a murmur at the apex preceding the first sound of the heart was an aortic regurgitant, due to blood running down on the posterior wall of the heart. Shortly afterward, however, he met with a case of presystolic murmur, and examined the patient many times. She died of pneumonia, and at the autopsy he found stenosis of the mitral valve, there being only a button-hole slit. Since that time he had never questioned the existence of a presystolic mitral murmur, nor had he had any doubt as to the anatomical conditions which produced it. Nor had he regarded it of specially serious import unless it were developed from an endocarditis. A large number of the murmurs were congenital. He had seen this illustrated in three members of the same family. Such patients suffered only after violent exercise or pulmonary congestion. He thought these murmurs could be distinguished by their characters.

As to pulsation of the liver, it was not infrequent in connection with cardiac hypertrophy, but Dr. Loomis had never seen expansive pulsation of the liver except when there was sufficient tricuspid insufficiency to produce a pulsation in the jugular vein.

Dr. Loomis dwelt upon the importance of not laying too much stress upon the presence of cardiac murmurs. He was convinced that they might be absent, or their presence be not recognized in a person who, after some sudden exertion or blood strain, got up cardiac dilatation, and then the murmurs might appear.

Dr. Loomis asked Dr. Janeway, who had referred to ulcerative endocarditis, whether he regarded it as an infectious or a non-infectious disease; whether primary or secondary?

Dr. Janeway replied that there were some cases of undoubted secondary ulcerative endocarditis. Others, so far as could be determined, were primary, there being no other lesion to which it could be traced. There were other cases in which we might be left in doubt as to whether the other lesions coexistent with the ulcerative endocarditis preceded it or were secondary to it.

The President asked whether a murmur was to be considered as always present in ulcerative endocarditis.

Dr. Janeway replied that it might not be present.

The President said he anticipated such would be the reply, for he was quite sure he had seen a case of ulcerative endocarditis in which there was no murmur. Perhaps it was because the vegetations were so near the base of the valve that they produced no vibration.

Dr. Janeway remarked that he had seen many vegetations in cases in which there was no murmur, and the absence of murmur was due to cardiac weakness. As to the diagnosis of mitral stenosis, it was sometimes difficult to distinguish between this condition and simply a prolonged first sound of the heart.

The Academy then adjourned.

Correspondence.

OUR PARIS LETTER.

MORE ABOUT PASTEUR'S METHODS.

Paris, May 21, 1886.

It has been objected that submitting the rabid spinal cords to the influence of dry air has the effect of gradually lessening their virulence, and finally entirely destroying it. M. Pasteur has ascertained by experiment that this is not the case. Experiments made on rabbits proved that the cords prepared in dry air were poorer in quantity of virus, but not in quality. He further ascertained that the rabid virus was composed of two distinct substances: one, living, capable of developing in the nervous system; another, deprived of vitality, but, if present in a sufficiently large proportion, capable of arresting the development of the former. Although a great deal has been already written concerning the manner in which M. Pasteur inoculates human subjects for hydrophobia, yet a short account of them here may be acceptable to your readers. Patients who come from all parts of the world, and who are generally of the lower classes, reside in small hotels and lodging-houses in the neighborhood of the École Normale, in the Rue d'Ulm, where M. Pasteur's laboratory is situated.

When the patients arrive at the laboratory for inoculation, they are received either by M. Pasteur or by one of his assistants, and their names and addresses are taken. A certificate from a veterinary surgeon or medical man is required, stating that the dog was mad. Their wounds are examined; if they have not been bitten on the face or hands, and their clothes be not lacerated by the animal's teeth, so that the virus has not passed into the wounds, they are sent away. In some cases, however, a certificate is not produced and the dog has been lost sight of; to these M. Pasteur gives the benefit of the doubt and inoculates them, his argument being that it is only humane to place these people beyond danger, especially as it is highly probable that the dog which inflicted the bite was mad. The inoculations are performed each day

from 11 A.M., and last about an hour or more, according to the number of cases, the average being from eighty to one hundred in that time. M. Pasteur calls in the patients one by one, according to the series previously arranged. Series No. 1 is that which has to be inoculated for the first time, No. 2 for the second, and so on. The accommodation for these inoculations is very limited—a waiting-room and an inoculating-room; the former is so small that a number of the patients are obliged to wait outside. Even the inoculating-room is crowded, not only with patients, but with a number of medical men and others who come to witness the proceedings.

At one end of the inoculating-room is a table on which are placed different glasses, covered with a piece of gutta-percha sheeting, which contain the different solutions of virus in sterilized broth. The inoculations are performed by Dr. Grancher, who has two assistants; one fills and hands him the syringe, the other helps the patient. When an entire series is assembled Dr. Grancher performs the inoculations one day in the right hypochondriac region, another in the left, and so on alternately. This precaution is observed to prevent irritation or inflammation consequent on the introduction of the virus. To avoid the trouble of undressing the patients lift their shirts from over the side, thus exposing the part to be inoculated. The inoculator seizes the skin, lifts it up, plunges the needle of the syringe deeply into the areolar tissue, and presses the piston down to the end. The dose for adults is a Pravay's syringeful (about a cubic centimetre) of the virulent mixture; for children the syringe about half or three fourths full, according to their age. The first inoculation is made with virus that has been kept in broth for fourteen days, the second inoculation with virus of thirteen days, and so on, until at the end of ten days a virus of five days' attenuation is used. This completes the ten inoculations which are supposed to be sufficient to preserve the patient from hydrophobia; that is to say, that which is caused by the bite of a dog.

In cases of bites by rabid wolves M. Pasteur repeats the series of ten inoculations three times over. In a room close to the inoculating-room, a surgeon (M. Terrillon) dresses the wounds resulting from the bites. When the wounds are of so serious a nature that the sufferers are obliged to be treated at a hospital or in their own lodgings, M. Pasteur, or one of his assistants, goes to make the inoculations. The rabbits intended as subjects for the inoculations are kept in wire cages, some to be inoculated, others which have already been operated upon; of these three or four die daily. The mode of death in the rabbit is quite different from that of man—they die of paralysis, without a struggle; in some very rare instances, however, they die of symptoms resembling those observed in the human being. Two dead rabbits are taken daily to the laboratory. The spinal marrow is taken out and cut into pieces about four inches long; one end is attached to a piece of fine wire, the other end of the wire being fixed to a stopper, and placed in a glass bottle prepared for the purpose. The preparation of the bottle consists in heating it to about 150° C., cotton wool being placed in the mouth and at another opening at the bottom of the bottle. A thick layer of caustic potash is placed at the bottom of the bottle. A few hours after the piece of spinal marrow has been fixed in the bottle it acquires a glazed appearance, as if it had been varnished. A small fragment of this is put in sterilized broth and kept there for fourteen days; this then serves for the first inoculation, as mentioned above.

The operation of inoculating the rabbits is done in the following manner, which I here describe even at the risk of repeating what may have been before given. A healthy rabbit is placed on a board lying on its abdomen; its hind legs are fastened to two lateral pegs, and the same is done to the forepaws. The hair is cut off its head to the extent of about half-a-crown. Chloroform is administered to the animal until it becomes quite insensible. A clean incision is then made lengthwise with a sharp bistoury previously dipped in a solution of carbolic acid. The lips of the wound are kept apart by an eye dilator, any blood is mopped up with fine blotting-paper also dipped in a solution of carbolic acid, and a revolving trephine is placed perpendicularly on the bone; in a few turns a small disk of bone, of about the size of a threepenny piece, is cut through, and extracted with a curved needle, also disinfected. The dura mater is thus exposed. A fine Pravay needle is then inserted under the membrane, and two or three drops of a strong solution of the virus are injected. The dilator is removed, the skin sewed up, the ligatures which fasten the legs are removed, and the rabbit is replaced in his cage. On the seventh day the rabbit begins to feel the effects of the inoculation, and dies invariably on the tenth day. Two rabbits are thus inoculated every day, and two die every day, so that a supply of virus is kept up for inoculating rabbits and patients. The inoculations in the human subject are sometimes followed by a slight œdematous redness, but no evil results have as yet been noticed.

Whatever may be thought of M. Pasteur's anti-rabic inoculations, I shall conclude this letter with his last report to the Academies of Sciences and of Medicine. "The number of persons inoculated for hydrophobia was, on April 4th last (the date of the report), 950. Of this number 912 were bitten by mad dogs, and 33 by wolves, the latter being all Russians. The patients of the first category, with the exception of the little girl Pelletier, who, it will be remembered, died after a few inoculations, are all doing well. More than half of that number have passed the dangerous period. Since I began these inoculations I have learned that the mortality caused by the bite of rabid wolves was very considerable. Very frequently this mortality is 100 per cent., and the duration of the incubation is always very short, being sometimes only thirteen or fifteen days. Very frequently also this duration does not exceed eighteen to twenty days. the bite of the dog being rarely of such short duration. Six deaths have occurred among those who have been inoculated, without including the little girl referred to above. The six cases were Russians, five of whom were men bitten by wolves, and the other a woman bitten by a mad dog, all of whom died of hydrophobia, and in whom also the wounds were of a very grave nature. These statistics present a great deception to hostile persons, such, for instance, as the anti-vaccinators. This is my profound conviction, and I believe that there can be no possible doubt regarding the method, as the persons adverse to it cannot contest the results which I have indicated, any more than the experiments which repose on the *ensemble* of these results."

There is no doubt that there is, and will for some time be, a good deal of scepticism as to the efficacy of this new method; in the meantime M. Pasteur, who is looked upon as one of the greatest benefactors of the age, is being loaded with honors, and money is flowing in from all parts of the globe for the establishment of the Pasteur Institute. The last list of the subscriptions, which has just appeared in the *Journal Officiel*, shows a total of 711,813 francs. I may here mention that among the latest donors was Mr. Morosini, of New York, who, you are aware, brought his daughter over to Paris to undergo M. Pasteur's treatment for the bite of a mad dog. He subscribed $1,000 toward the institute, as M. Pasteur accepts no fees, and he presented Dr. Grancher, M. Pasteur's inoculator, with a handsome piece of silver plate. Miss Morosini is, I am glad to say, doing well, and has suffered no inconvenience from the inoculations.

THE INJURIOUSNESS OF NATURAL GAS AS A FUEL.

SIR: I have noticed several articles in the newspapers, and a short one in THE MEDICAL RECORD for April 3d, relating to the "Injuriousness of Natural Gas as a Fuel,"

especially as irritating the respiratory organs. I live in a portion of country entirely supplied with natural gas. Everybody burns it. The houses are lit with it. Within a radius of one mile I can count two hundred oil-wells, all producing large quantities of gas. We consider ourselves quite free from respiratory and pulmonary diseases. It is the prevailing opinion among the laity here that gas is of considerable therapeutic value in lung troubles. At all events, there is no evidence that gas, diluted with air, is injurious to the lungs. I have conversed with a number of physicians in Bradford and other parts of McKeon County, and all, as far as my investigations are concerned, agree in considering natural gas non-injurious to the lungs. If pneumonia recently occurred in a town in this State, near Pittsburg, about the time natural gas was introduced as fuel, it was a coincident, and no fault of the gas. I have burned it, and live in a country where the air is, to a certain extent, impregnated with it, and have, for nearly ten years, and know whereof I speak.

Yours very truly,
H. A. CANFIELD, M.D.

GILMOR, PA., April 7, 1886.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 23 to May 29, 1886.

SMITH, ANDREW K., Lieutenant-Colonel and Surgeon, WOODHULL, ALFRED A., Major and Surgeon, and KIMBALL, JAS. P., Captain and Assistant Surgeon. Detailed as board to assemble at U. S. Military Academy, West Point, N. Y., on June 1, 1886, to examine into the physical qualifications of members of the graduating class and the candidates for admission to the Academy. S. O. 119, May 21, 1886.

HARTSUFF, ALBERT, Major and Surgeon. Detailed as member of a board appointed to meet at U. S. Military Academy, West Point, N. Y., on June 1 and August 25, 1886, to examine into the physical qualifications of members of the graduating class and the candidates for admission to the Academy. S. O. 121, A. G. O., May 25, 1886.

Par. 7, S. O. 120, A. G. O., May 24th, revokes so much of par. 12, S. O. 119, A. G. O., May 21st, as details Surgeon Alfred A. Woodhull as member of medical examining board to meet at West Point, N. Y., June 1, 1886.

WINNE, C. K., Captain and Assistant Surgeon. Granted leave of absence for twenty days on surgeon's certificate of disability. S. O. 34, Department of California, May 17, 1886.

KILBOURNE, HENRY S., Captain and Assistant Surgeon. Assigned to duty at Vancouver Barracks, Washington Ter. S. O. 80, Department of Columbia, May 15, 1886.

APPEL, A. H., Captain and Assistant Surgeon. Ordered for duty at Fort Reno, Indian Ter. S. O. 52, Department of Missouri, May 24, 1886.

BENHAM, R. B., Captain and Assistant Surgeon. Ordered for temporary duty at Fort Omaha, Neb. S. O. 56, Department of the Platte, May 24, 1886.

JOHNSON, R. W., First Lieutenant and Assistant Surgeon. Ordered for duty at Fort Adams, R. I. S. O. 45, Division of the Atlantic, May 25, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 29, 1886.

DICKSON, S. H., Passed Assistant Surgeon. Detached from the Naval Academy and to the Constellation.

SIMON, W. J., Surgeon. Detached from the Naval Academy and to the Constellation.

KIDDER, B. H., Surgeon. Detached from the Powhatan and to the Tennessee.

RHOADES, A. C., Surgeon. Detached from the Tennessee, proceed home and wait orders.

CERDEIRO, F. J. B., Assistant Surgeon. Detached from the Powhatan, proceed home and wait orders.

CLARK, J. H., Surgeon. Ordered for examination preliminary to promotion.

HUGG, JOSEPH, Surgeon. Detached from the Minnesota and granted sick leave.

BEAUMONT, H. N., Surgeon. Ordered to the Receiving Ship Minnesota.

LAW, H. L., Surgeon. Detached from the Wabash and granted sick leave.

HENRY, CHAS. P., Assistant Surgeon. Ordered to the Receiving Ship New Hampshire.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 29, 1886 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.

THE HAPPY MEDIUM IN MEDICATION.—Dr. S. C. Dumm, of Columbus, says : "In THE MEDICAL RECORD of May 15, 1886, there occurs this sentence, said to be from the lips of the late lamented Austin Flint, 'that fame would attend that author who would write a work on the non-medicinal treatment of diseases.' Also that a Canadian author said he believed 'that the erection and endowment of a thoroughly equipped hospital where medicinal treatment should never be used, unless an occasional anæsthetic, would be of the greatest possible benefit to mankind and to the science of medicine.' The regular medical profession are, we are sorry to say, as prone to run to extremes now as formerly. There was a time when the great Rush bled for all kinds of disease, the weak and the strong, without regard to effects, and thus brought discredit on a no doubt efficient remedy in many diseases. The prejudice engendered by this indiscriminate use of a powerful method of treating inflammatory diseases has not been removed, and the practitioner who would venture his reputation on an occasional case where needed, should he be so unfortunate as to lose his case, would not soon recover from the influence. The preparations of mercury, by the way, the most useful of remedies, was brought into discredit in the same way. The profession ran headlong into an excessive use of this most potent remedy, and had it not been for its wonderful efficiency in syphilitic diseases it would have been consigned to the same grave as that of bleeding. There is too much of a tendency to ignore drug treatment, hence homœopathy and tomfoolery flourishes, and it will do so as long as men run to extremes in that way. Why is it, we ask in all candor, if diseases will get well without medicines, that when the sugar doctor finds that he can't get through with his remedies he resorts to those of the regular practitioner? The only benefit we can see that could be derived from a hospital in which medicines are withheld, is that a line could be drawn between those cases which need medi-

cines and those who would probably get well in time without them. But, while this process of experimentation was going on it would be a curse to those who imperatively needed medicines. There is no use for physicians to try to ignore the use and need of drugs when every day they prescribe and see their great benefit, and we assert here, with due respect for our great men, that they will not practise what they preach, and we don't believe that in a sober second thought they would recommend the disuse of drugs. We don't believe in the indiscriminate use of drugs, but we do believe that there is a great midground on which physicians should stand, withholding where not needed and prescribing where needed. If physicians to prescribe drugs as well as hygienic measures are not needed, then why not do away with the title of M.D., and let the hygienists run the thing?"

The Pure and the Impure.—Dr. Walter F. Morgan, of Leavenworth, Kan., writes: "For the past three years I have been a constant reader of your journal, and have admired its tone upon the Code question and its method of treating the moral aspect of medical subjects. I have often told my medical friends that it was—all things considered—the best medical journal I ever had the good fortune to see, and this was said in all sincerity. Either The Record must retrograde, or *I* must retrograde, to prevent our being companions to the end of life's journey. With these views, perhaps, you will not be surprised that I ask the privilege of protesting against some things in the article upon 'Gonorrhœa' in your issue of the 8th ult., and I would do so in the name of your own scathing editorials, which have often consumed sexual filth in the fires of pure reason, common sense, and the highest physiological knowledge. Every healthy, honest man may admit, with Ben Franklin, that 'the sexual passion is hard to control.' So much the more does it seem to be his duty and honor to see that he *does* control it, and it is plainly the highest duty of the physician to preach the truth to those who have not yet learned this lesson, viz., that no man, under any circumstances, or form of treatment, can escape punishment, be it more or less, who uses his sexual organs for any but their legitimate purpose—the procreation of his kind. For, as Emerson says, 'A man may boast that he has learned how to evade nature's laws, but the brag is on his lips—the conditions are in his soul.' Hence, is it not evident that when a physician takes pains to speak of his gonorrhœal patient as his 'friend,' and of the wretched woman as bestowing her '*favors*' on several of his patients, and of his delightful, euthanasic methods of prompt relief, it is only the song of the siren, leading his deluded victims on to their destruction? The doctrine taught by some respected specialists, viz., that a 'moderate use of the sexual organs is essential to health,' has ruined many young men and will ruin many more, and women too—in accordance with the law of supply and demand. The true principle of evolution shows that so far as men apply those scientific and rational rules of generation to themselves which they do to domestic animals, the parent is able to beget offspring somewhat better than himself, and hence the gradual improvement of the race and more frequent realization of the great desideratum, 'A sound mind in a sound body.' It seems to me that when a physician forgets that his chiefest and highest functions are to prevent disease and to teach the beautiful and beneficent laws of nature, he then also forgets the best interests of both himself and his profession, even though he cures his patient, as he is bound to do, by the most skilful methods at his command."

Wiring the Patella.—Dr. Robert T. Morris, of this city, writes: "In The Medical Record of July 18, 1885, was published a description of the operation of wiring the patella, and three cases were described in detail. One of the patients, Mr. G. G——, was shown to have had a poor result because of the stiffness of the knee, which persisted in spite of treatment. Last week the patient came to my office to say that he could easily bend his knee to a right angle, and that his only discomfort was due to the presence of the wires beneath the skin, which prevented him from kneeling, and which made him cautious about striking the knee against any solid body. I could feel the two little knobs of wire beneath the skin, and shall ask the patient to let me remove them later. Two years and a half have elapsed since the operation, and the patient says that his knee remained quite stiff until four or five months ago, when it rapidly began to 'limber.' At present flexion to a right angle can be made without pain. Treatment had not been employed since the date of my former report. There is evidently bony union between the fragments."

Dr. Dawson on Infant Food.—Dr. B. F. Dawson, of this city, writes: "In the report of the discussion of Dr. F. A. Burrall's paper, in transactions of the Academy of Medicine, published in The Medical Record, pages 509–510, I am quoted as saying a little less than I actually did, and in consequence my remarks, as printed, somewhat misrepresent my opinions as expressed at the meeting. The second paragraph of my remarks should read as follows: 'Cow's milk was all that was necessary, with something added to prevent the coagulation of the casein into hard, large lumps, as barley or oatmeal water; if anything more was to be added it should not be water, but fat—for example, cream, or when there was more or less constipation a piece of pure fresh butter as large as the kernel of a hazel-nut at each meal. He said that if an infant could only be looked upon as an animal, whose mother, in order to provide for herself, must leave it alone without food for more or less time, all those who had to do with the rearing of children would get along much better than they did.'"

The Santa Lucia Asylum for the Blind.—We have received the report of this institution, which is not only an asylum for the blind, but also a hospital for the treatment of diseases of the eyes. The director is Dr. Santiago de los Albitos, of Madrid. The number of patients treated in the institution during the year 1885 was 1,616, and there were 198 operations performed.

Dr. Edouard Fournier, editor of the *Revue Médicale*, of Paris, has recently died. He was physician to the Institute for Deaf-Mutes, and was well known as a specialist in the treatment of diseases of the larynx. He was one of the strongest and most able opponents of the bacteriological school, and loved to be styled a follower of traditional medicine.

Spanish Society of Laryngology, Otology, and Rhinology.—An association has recently been formed in Barcelona, having for its object the promotion of studies and original work in the branches of medicine mentioned in its title. The first annual meeting will be held in Barcelona from the 24th to the 29th of May. The committee on organization consists of Drs. Luis Suñé, Pedro Verdós, and Agustin Basols, of Barcelona; Rafael Ariza, of Madrid, and Ramon de la Sota, of Seville. There will be both foreign and Spanish members, each enjoying equal privileges. The initiation fee is placed at 15 pesetas ($3), and the annual dues at $2, or 10 pesetas.

A Case of Hermaphrodism is reported by Dr. Sahn in *Hygiea* for March, 1886. The individual had been brought up as a girl, and when first seen, at the age of twenty-three years, by the author, was dressed as a woman, and was so regarded by the family. The patient sought advice because of amenorrhœa, and an examination of the genital organs showed complete hypospadias. The penis was small, and the testes were situated one on each side of this organ. The breasts were undeveloped, the voice was that of a man, and there was a sufficiently strong beard to require daily shaving.

Some Fallacies in Regard to Diet.—1. That there is any nutriment in beef-tea made from extracts. There is none whatever. 2. That gelatine is nutritious. It will not keep a cat alive. Beef-tea and gelatine, however, possess a certain reparative power, we know not what. 3. That an egg is equal to a pound of meat, and that every sick person can eat them. Many, especially those of nervous or bilious temperament, cannot eat them; and to such, eggs are injurious. 4. That because milk is an important article of food, it must be forced upon a patient. Food that a person cannot endure will not cure. 5. That arrow-root is nutritious. It is simply starch and water, useful as a restorative, quickly prepared. 6. That cheese is injurious in all cases. It is, as a rule, contra-indicated, being usually indigestible; but it is concentrated nutriment, and a waste-repairer, and often craved. 7. That the cravings of a patient are whims, and should be denied. The stomach often needs, craves for, and digests articles not laid down in any dietary. Such are, for example, fruit, pickles, jams, cake, ham, or bacon, with fat, cheese, butter, and milk. 8. That an inflexible diet may be marked out, which shall apply to every case. Choice of a given list of articles allowable in a given case must be decided by the opinion of the stomach. The stomach is right, and theory wrong, and the judgment admits no appeal. A diet which would keep a healthy man healthy might kill a sick man; and a diet sufficient to sustain a sick man would not keep a well man alive. Increased quantity of food, especially of liquids, does not mean increased nutriment; rather decrease, since the digestion is overtaxed and weakened. Strive to give the food in as concentrated a form as possible. Consult the patient's stomach in preference to his cravings; and if the stomach rejects a certain article, do not force it.—*Technics.*

A Self-performed Laparotomy.—Dr. B. Raniero, in a letter to the *Raccoglitose Medico* for April 10, 1886, reports the case of a woman, twenty-five years of age, who was pregnant, and desired to conceal the fact. Not being able to rid herself of the child, in a fit of desperation she seized a bread-knife and made a deep incision, five inches long, on the right side of the abdomen, and extracted through the opening thus made a full-term fœtus. The child was dead, the knife having severed its head from the body. The woman bound up the abdomen with a cloth, and then walked two miles to the village of Viterbo, remaining there five hours, and returning again to her home, which she reached seven hours after the infliction of the wound. The pain then became so severe that she fainted, and upon returning to consciousness vomiting occurred. The wound was opened and the greater part of the small intestines were protruded. Medical aid was then sought for the first time; the intestines were returned, the wound closed by sutures, and the patient recovered without any untoward symptoms.

A Literary Effort.—A Cincinnati physician returned a death certificate to the authorities, giving the cause of death as follows: "She dide with Liver dease & New Monei."

A Cause of Inebriety in Switzerland.—In a recent discussion at the Geneva Medical Society, Dr. Lombard stated that one of the most potent causes of inebriety in Switzerland was the scarcity of milk. There was no dearth of cows, but so much condensed milk, not to speak of other lacteal preparations, was made and exported, that fresh milk was a rare and costly article. Its place was largely taken by alcoholic fluids. Even children were given bread soaked in brandy.

Abdominal Dulness Varying with Position.—In an article in *La Riforma Medica*, Nos. 76, 77, and 78, 1886, Professor G. B. Queirolo writes that he was led to make a diagnosis of ascites, and to tap the abdomen, by reason of the presence of dulness or percussion, the level of which varied according to the position of the patient. He found no fluid present. In pursuing his researches further in order to discover a cause for his error, he found that this sign is normally present in healthy persons, though, perhaps, not to so marked a degree as in the case of intra-abdominal effusions. It also differs from the dulness caused by fluid within the peritoneal cavity, in that it varies from day to day, being now greater in extent and again less. This physiological dulness, as he terms it, is caused, he thinks, by the gravitation of the fluid contents of the small intestines to the lowest point in the abdominal cavity.

The Treatment of Singultus.—Dr. Robert B. Wilson, of 529 Lexington Avenue, writes: "I wish to say one word in regard to the treatment of that simple but sometimes very obstinate complaint, singultus. I have tried a remedy which works wonders, at least in simple cases, though I have never had the opportunity of trying it on cases of several days' standing. The remedy, also, is so simple that I suppose it is not new, yet I have never seen it recommended for the complaint, although it is very probable that it has been. It consists simply in giving the patient a good pinch or two of 'catarrh snuff' to produce immoderate sneezing. I have seen the happiest results from it in hiccough of as much as two days' persistence. A simple 'catarrh snuff' for the purpose may be made by mixing one part of powdered veratrum album with about four parts of pulverized licorice-root. Of course it may fail in very stubborn cases, but it never has thus far with me."

Contagion of Tuberculosis.—At a recent meeting of the Société Médicale des Hôpitaux, M. Vallien read a report on the contagious properties of tuberculosis. The Society sent a list of questions to 10,000 medical men, and received 173 answers. Those who answered were classified as follows: 57 believed in contagion, 57 disbelieved in it, 7 gave doubtful replies, and 2 were incomprehensible. Of 439 cases forwarded, 213 suppported the hypothesis of contagion, and 226 were against the theory. The 213 cases favorable to the theory were as follows: 107 were husbands and wives, 71 near relations, 18 the offspring of phthisical parents, and 16 were distant relations. In one instance the disease was said to have been transmitted from a master to his dog. Heredity is an important factor in the propagation of tubercle. Tuberculosis is, the report states, more frequently inherited from the mother than from the father. Inherited tuberculosis is manifested sooner than when contracted from proximity with the contagious principle. It is difficult to ascertain what is the exact proportion of cases due to contagion. It is roughly estimated to be one in ten among the well-fed classes; among the poor classes it is much greater. Data are at hand which indicate that phthisis has been imported into isolated localities and islands by inhabitants from neighboring countries where the disease existed.

Writers' Cramp and Fracture of the Clavicle.—"At a recent meeting of the London Clinical Society a unique case was described by Mr. Arthur Barker. The patient was a boy, aged twelve, in whom fracture of the clavicle had occurred before birth, and had remained ununited. A false joint formed, and there was free movement and no inconvenience till about three years ago, when the patient began to suffer from pain down the right arm, and a sense of weight in it. Symptoms resembling those of 'writers' cramp' then came on. In August last Mr. Barker resected (antiseptically) the false joint, wired the cut surfaces together, and put up the shoulder and arm in a plaster-of-Paris jacket. The wound healed in a fortnight without any suppuration. In another fortnight the corset was removed, the scar being sound, and the bone firmly united with callus. Shortly after, he was given some writing to do, and the former symptoms were found to have disappeared."

THE IMMEDIATE CLOSURE AND RAPID CURE OF FISTULA-IN-ANO.[1]

By STEPHEN SMITH, M.D.,

THE possibility of a prompt cure of fistula-in-ano is a great advance in the treatment of this hitherto troublesome affection. Every surgeon must have met with cases which resisted the old method, and failed altogether to heal. And even when those having a large abscess cavity finally healed after free incision, there was often a deep cicatrix, which was a source of constant irritation from the tendency to the accumulation of filth in the deep sulcus. Occasionally there was a certain troublesome defect in the action of the sphincter, which remained as a permanent disability. In these latter days of rapid improvement in the methods of operations, it has naturally occurred to many surgeons that fistula-in-ano might be treated successfully by the immediate closure of the wound, provided the track and abscess cavity were properly prepared, and then sutures were employed so as thoroughly to approximate the surfaces. It has been performed successfully in this country by Drs. Emmet, Weir, Lange, and Chamberlain, of this city, by Dr. Jenks, of Chicago, and by several surgeons abroad. In most instances these surgeons have operated without any previous knowledge of the work of other operators. The simplicity and the success of the operation warrant the effort to give it greater prominence than it has yet received.

Attempts have been made, heretofore, to cure fistula-in-ano by incision of the track, followed by the dissection of the lining membrane, but with indifferent success. It is only when the surfaces are quite firmly brought together and maintained in apposition, that union takes place with any greater certainty and rapidity than by the former method. My attention was first directed to this method of operating on the appearance of the first edition of Dr. Emmet's work, in 1879. I was impressed, while reading that work, with the explanations of the method of closing a lacerated perineum involving the sphincter ani, and with the accompanying illustrations. I had at that time under observation a case of fistula-in-ano, which had been laid open freely six months before, but had failed of union. The line of incision was slightly to the left of the median line, but the depth of the wound and its large granulating surfaces reminded me of some of the conditions of a lacerated perineum of long standing.

The suggestion that this wound, involving the sphincter, was amenable to a somewhat similar method of treatment was very natural. The result proved the truth of the suggestion. It was not difficult to dissect away the granulating surface, and to accurately close the wound with sutures not unlike those used for the lacerated perineum. Union promptly occurred. Since that time I have operated on a number of cases of fistula, including every variety of form, and nearly every condition of patient, with a degree of success which commends the procedure to my confidence.

The principles which should be borne in mind in the operation are: 1, complete removal of the lining membrane of the fistula and of the abscess cavity which may exist; 2, accurate and permanent adjustment of the opposing surfaces; 3, thorough antiseptic treatment of the wound.

The details of the operation are simple, but they must vary somewhat according to the peculiarities of each case. After considerable experience, I have adopted the following general plan: The patient is prepared for the operation by taking an ounce of castor-oil for two succeeding days before the operation, omitting the last day, on which he takes an opiate at bedtime. The diet should be milk. It is intended to keep the bowels quiet for four to six days after the operation. The patient being anæsthetized, the parts about the anus are thoroughly washed with soap and water, then carefully shaved, and finally irrigated with bichloride solution. This douche is also thrown into the rectum and the index-finger is introduced and swept around the folds of the rectum, in order that the mucous membrane may be relieved of any matters lodged in that region. A clean sponge, wrung out of the bichloride solution and having a string attached, is next introduced into the rectum to prevent any matter from the bowel escaping and soiling the wound. The patient is placed on the back or side on which the fistula opens. If the fistulous passage is direct it is incised in the usual manner. If there is an abscess cavity this is opened to the full extent, in order to give free access to the lining membrane. The lining membrane, or so-called pyongenic membrane, is then carefully dissected away, throughout both the cavity and the fistula. The rapid and permanent healing of the wound depends largely upon the thoroughness with which this tissue is removed. It is generally very dense, and can only be completely dissected off with a sharp scalpel or scissors cutting well at the point. In some of my early operations I resorted to the curette, and endeavored to destroy the membrane sufficiently to secure union, but the operations were unsatisfactory till I removed it with the knife or scissors. When it is completely removed, the ragged, or thin and purple, margins of the wound are cut away so as to have clean and healthy surfaces for apposition and union. There is in some cases considerable hemorrhage from small arteries, which must all be ligated before the wound is closed. The first step in the closing of the fistula and abscess is to secure perfect apposition of the margins of the wound within the rectum. To effect this object an assistant should introduce an index-finger well into the rectum, and then, bending it as a hook, extrude the bowel, which is readily effected. The whole track of the fistula is thus brought into view, and the surgeon has full control of the wound. To obtain prompt union it is necessary to evert the edges of the mucous membrane, and bring the deeper cut surfaces into contact. The success of the operation depends upon securing complete and firm closure of that portion of the fistula which involves the mucous membrane. The first sutures, therefore, should be so applied as to bring the deep surfaces together and evert the margins of the mucous membrane. To effect this object I take a large-sized carbolized silk ligature, or catgut prepared with chromic acid, and attach a needle having a slightly curved point to each end. These materials are preferred because they will not yield as does the ordinary catgut, and allow the margins to separate before union takes place. One needle is now passed just above the highest point of the incision, and from a fourth to half an inch from the margins of the wound,

[1] Read at a meeting of the Section on Surgery, Academy of Medicine.

and the thread is drawn through to its centre. The needles are then passed in opposite directions at intervals of about half an inch, in the same manner as the saddler takes his double stitch when two pieces of leather are held in a vice and united. If the fistula is simple and there is no abscess cavity, the stitches are continued to the external extremity of the incision, making a continuous suture on each side of the wound. They are now tightened sufficiently to bring the two surfaces into apposition and slightly evert the margins of the mucous membrane, but without any strain. The ends of the ligature are then given to an assistant, who by moderate traction draws the entire fistulous track outside. The margins of the wound are now nicely adjusted with a continuous suture commencing at the upper extremity of the wound. At the external extremity of the wound a drainage-tube is inserted. When the margins of the wound are closed the ends of the suture are tied. The operation is completed by passing two or three large carbolized silk ligatures entirely under the fistula, and tying them over an iodoform gauze pad rolled firmly and laid along the wound. The object of these last ligatures is to bring the deep portion of the fistula in suitable apposition. During the operation irrigation with the bichloride solution is continued, and idioform gauze is applied as an external dressing. The sponge is finally withdrawn from the rectum, and a suppository of opium inserted. The diet should be milk, and opium should be continued daily for from four to six days to keep the bowels quiet. The patient should remain in bed, and at first should remain recumbent, with the limb straight. In some cases I have applied a binder about the hips to prevent movements, where the patients were inclined to be restless.

If there is a large abscess cavity and, as often occurs, irregular, as in the horse-shoe fistula, I have always entered the cavity at the external opening, then laid it open freely throughout its entire extent, and finally have opened the internal fistulous passage at the point where the cavity communicated with the interior of the bowel. Such an abscess presents a large, irregular, deep cavity, having an opening into the bowel sometimes on the side opposite the point where the cavity opens externally. These cases require much care, for the cavity to be closed is enormous, but they may be perfectly healed by one operation, if great pains are taken to dissect out all the false membrane, and to adjust the sutures so as to bring the surfaces into apposition. The internal fistulous track is closed by the same suture as the simple fistula. The abscess cavity may be closed by one of two methods: 1. The same double, continuous saddler's suture may be employed, but it should be taken farther from the external margin of the wound, in order to bring as much strain as possible on the deep parts of the wound. Upon the inside, along the margin of the anus, it is well to enter the suture close to the border of the mucous membrane. This suture is continued to the external extremity of the wound. The continuous suture is then applied to the wound, and the same dressings applied. It sometimes happens that, even in the horse-shoe fistula, when the suture is finished, two or three sutures, either large thread or wire, inclosing the entire cavity, may be passed completely around it, thus aiding in approximating the deep surfaces. 2. The second method is by interrupted sutures passed the same as the suture in the lacerated perineum, that is, completely around the cavity. This suture is more difficult to employ than the former, but it is more successful. With this suture I have found no difficulty in closing at one operation an old rectal abscess of large size, which had no communication with the rectum.

In simple fistula having no cavity between the external and internal opening, I have found it possible to save incision of the sphincter by incising the sinus to the sphincter, dissecting away the false membrane up to the internal opening, and then by means of the double suture to bring the raw surfaces together. The suture is to be applied within the anus, the parts being partially extruded by the finger of an assistant hooked within the anus. The same result has been obtained by Dr. Emmet, and I believe by others. In two cases the internal opening was more than two inches above the anus, one indeed being three inches. In both cases the sinus was incised to its fullest extent, and the same form of suture employed with the best results. In my first operations I employed the single-valve speculum, but I found it by no means as useful as the finger of an assistant. When the internal opening is high up, with strong loops of ligature thread inserted into the margins of the wound at the anus, the whole track can be readily drawn down within reach of the operator.

The conclusion which I have reached from my own experience is that fistula-in-ano and old rectal abscess cavities, whether communicating with the bowel or not, can be cured by removal of the lining membrane and the application of a proper suture, in a period varying from eight to fourteen days.

I may add that I have found deep fissures of the anus readily cured by excision of the track with its cicatricial lining, and accurate closure with carbolized silk ligature, the parts being first carefully shaved and cleansed with bichloride solution, and the wound dressed with iodoform gauze.

THE FUTURE INFLUENCE OF SURGERY UPON OBSTETRICAL ART.[1]

By CHARLES CARROLL LEE, M.D.,

SURGEON NEW YORK STATE WOMAN'S HOSPITAL, ETC.

To those of us who practise obstetrics and gynecology —to those, even, who feel but a languid or a theoretical interest in these branches of medicine—nothing is more impressive than the rapid inroads of surgery into a domain heretofore deemed strictly medical.

Is this just or natural? Is it true, as has lately been said by a famous Scotch surgeon—himself among the most illustrious exponents of abdominal surgery now living—that "the restless surgery of to-day will let nothing alone; it has no patience, . . . and would attack all and sundry in some way or other, till one almost begins to think that individual responsibility has become old-fashioned and gone out of date?"

A most distinguished fellow of this Academy, whose counsel has been equally sought in this hall and in many anxious consultations in our practice, is known to deprecate this tendency of the day, and to feel it a mistake that gynecology should invoke the frequent aid of the knife, or obstetrics of the surgeon's scalpel.

I have thought it might be profitable, then, to invite your attention to this notable current of medical thought; and, for a few brief moments, to ask your consideration of so important a subject as the future influence of surgery and surgical resources upon obstetrics.

In the past it must be evident that obstetrics was practised as an art from the earliest ages. Although at first its methods were rude and uncouth, it kept pace with advancing civilization; and the history of every nation of Europe and of the East teems with evidence of this fact.

Thus, while Herodotus records the rough usages that surrounded the parturient woman among the Scythians and the nomadic tribes that were the forerunners of the Persian Empire, Egypt, which was then the fountain whence the arts and civilization overflowed the ancient world, possessed a cultivated medical body familiar with ordinary obstetrical measures, and even with the speculum and other supposed inventions of modern gynecology.

From Egypt the knowledge of medicine in general, and of obstetrics, passed to Greece and Rome; and

[1] Read before the New York Academy of Medicine, June , 1886.

Hippocrates, who was a contemporary of Herodotus, left in his "Aphorisms" many obstetrical suggestions which, for better or worse, profoundly influenced this branch of practice for more than a thousand years.

At this early date, and for centuries later, obstetrics and surgery were practised in common, but by degrees the former gradually passed into the hands of women.

In most serious complications, however, the surgeon was still consulted; and his functions extended from the performance of cephalic version to that of the Cæsarean section, which, in spite of many recent denials, was certainly known to the ancients; and, at least as a post-mortem expedient, was occasionally attempted.

As time passed, and as pure surgery extended its sphere in other directions, obstetrics became gradually a distinct specialty; its practice was again resumed by men all over Europe; and, during the last century, what had been a slowly maturing art was raised to the dignity of science, chiefly through the labors of Levret in France, and of Smellie and William Hunter in Great Britain.

The reproach and contumely that had hitherto attached to the "man midwife" was now rapidly swept away; and the purely obstetric practitioner occupied as honorable a position as any of his competitors.

Nevertheless, in cases of extreme or seemingly insuperable difficulty the surgeon's aid was still sought as a last resort; and before considering what may be the future outcome of this influence, it will be well to review briefly what has already been accomplished.

I begin with the Cæsarean section, to which reference has already been made.

The early accounts of this heroic measure are confused and no doubt unreliable, resting as they do only upon common tradition and the assertion of such writers as Pliny, whose veracity is never above suspicion.

The first unquestioned case of Cæsarean section was that of Trautmann, of Wittenberg, who operated in April, 1610, and whose patient lived nearly four weeks; although fifty years before this Ambroise Paré (1509–1590) and his pupil, Jacques Guillemeau (1550–1612), had described it—the latter specifying five fatal cases as the basis of his condemnation.

Dr. Harris, of Philadelphia, who is not only the greatest medical statistician this country has produced, but *par excellence* our authority upon this subject, believes it was accomplished more than a hundred years before Trautmann's case, by Jakob Nufer, of Siegenhausen, in Germany, who operated successfully in "or about 1500."

The indications for its performance may briefly be said to be excessive pelvic contraction, and insuperable obstruction by cancerous degeneration of the cervix or encroachment upon the lower pelvis by solid tumors.

If the mother be moribund, or just dead, and the child be known to be living, it may become advisable to effect in this manner the rapid extraction of the child.

The risk entailed may be inferred from the fact that in this country the general mortality of Cæsarean section has been sixty per cent., and in Great Britain eighty-one per cent. (Harris).

In fatal cases the causes of death are, first and chiefly, *delay*, with the shock and exhaustion entailed by it; second, peritonitis; third, septicæmia; fourth and very rarely, hemorrhage.

The customary method of operating comprises these four stages as tabulated by Lusk: "1, the incision through the abdominal wall; 2, the incision through the anterior wall of the uterus, and the extraction of the fœtus; 3, the removal of the placenta, the arrest of hemorrhage, and the cleansing of the peritoneal cavity; 4, the closure and dressing of the abdominal wound." All this is done with as complete antiseptic environment as possible, and with the usual assistants and appliances necessary in well-conducted laparotomies. Carbolized Chinese silk sutures, in preference to catgut or silver wire, should be used to close the uterine wound. If the placenta be found attached under this line of incision, which occurs about once in three cases (Stoltz), it must be quickly separated, or pushed aside, or cut through, so as to get rapidly at the child. Spiegelberg ("Handbuch der Geburtshülfe") met with this accident three times, and was finally compelled to cut his way through the placenta to save necessary time. Its risk is the immensely increased hemorrhage to which it gives rise; but as the extraction of the child is the only means of checking this, any process which facilitates that most rapidly is justifiable.

The uterus may also be pressed out through the abdominal wound, which renders manipulation easier and aids in preventing the escape of fluid into the peritoneal cavity.

Should the hemorrhage cease upon extracting the child, it will be best to wait a few moments for firm contractions before removing the placenta.

If this should not yield readily to gentle traction, the fingers should be passed into the cavity and the placental attachments separated.

As soon as the placenta and membranes can thus be extracted, and the remaining clots removed, the uterus contracts, or should be stimulated to do so, a drainage-tube passed down through the cervix and vagina, and the cut edges of the womb sutured with wire or carbolized silk.

The uterus is now replaced; the peritoneal cavity carefully and minutely cleansed; and the abdomen closed as after ovariotomy. If oozing from the uterine incision continues after it is sutured, a separate abdominal drainage-tube must be used. The after-treatment is as for other laparotomies.

Four modifications of this Cæsarean operation have lately been proposed, all of them originating in Germany.

1. Frank, of Cologne (*Centralbl. für Gynäkol.*, December 10, 1881), proposed a plan intended to secure perfect drainage, and to make the operation partly extra-peritoneal.

Thus the uterine incision is made low down anteriorly, and around the bottom of this the round ligaments of the womb are drawn together and secured with carbolized silk sutures, thus shutting off the incision from the peritoneal cavity; and from this blind pouch drainage is secured through the vagina.

In performing this operation, which is done antiseptically, the whole uterus is turned out of the abdominal wound before incising it. When it is emptied, a large drainage-tube is passed from the uterine cavity out through the vagina, and the uterine opening is closed above it with catgut; then the round ligaments are united in front, and a small drainage-tube carried from this pouch or pocket down through the vagina. After the tubes are in position the ligaments are sewed together, and the abdominal wound is closed in the usual way.

In one (fatal) case where this was done the peritoneal cavity was found at the autopsy to be quite free from blood or other fluids.

2. In the *Archiv für Gynäkologie*, bd. xix., 1882, Dr. Kehrer, of Heidelberg, proposed a plan, which Harris[1] says is not new (Dr. Wallace Johnson having suggested it one hundred years ago), of opening the uterus *transversely* in its lower third anteriorly, partly to avoid the placenta, which is rarely, if ever, implanted at this point, and partly to prevent the gaping of the uterine wound. The extraction is effected as usual; and in closing the wound he uses two sets of sutures—a deep and a superficial row. All antiseptic precautions are observed.

This he has twice done, once successfully; and, in the one fatal case, the uterine wound was found adherent wherever he had covered it with peritoneum.

3. Sänger, of Leipsic, proposed in 1881 (*Archiv für Gynäkol.*, bd. xix., tt. 3, 1882) another modification, which, as far as I can learn, has been performed eight

[1] As [illegible]

times in Germany, with the result of saving six women and eight children. When the abdomen is opened as usual, two strong loops of suture are passed through the edges of the wound at the upper end. Then the membranes are ruptured per vaginam, the uterus is pushed out through the abdominal wound and held vertically, while a carbolized rubber sheeting is adjusted around the cervix to prevent fluid from entering the abdominal cavity. The suture loops are now drawn tight, the uterus is opened longitudinally in front and its contents rapidly removed, while an elastic ligature (of tubing) is tightened around the cervix and the broad ligaments are temporarily clamped. Hemorrhage along the line of the wound is arrested by compression forceps. As the uterus contracts, a drainage-tube is passed from its cavity through the vagina, the peritoneum is dissected back from the cut edges, and a wedge-shaped strip of uterine tissue is pared off the edges of the incision. The free edges of the peritoneum are now turned in, and the uterine wound closed by deep sutures which include the peritoneal and muscular coats, but not the endometrium. Superficial stitches of catgut are added, so as to secure a perfect welt. The abdominal wound is dressed as usual.

Professor Leopold, of Dresden, has done this seven times; five times with, and twice without, the strip being sliced from the uterine edges; and at the Copenhagen International Congress he said that in future he would omit this as unnecessary.

In this country three fatal cases, I believe by Jewett, Garrigues, and Drysdale of Philadelphia, have been reported—all apparently because of the delay in resorting to it.

4. Cohnstein, of Heidelberg, has proposed (*Centralbl. für Gynäkol.*, bd. xix., tt. 3, S. 397, 1882) a plan which, so far as I know, has never been practised. This is to turn the uterus out of the abdomen, and to open it longitudinally behind instead of in front, and effect drainage through a tube perforating Douglas' pouch. The advantages claimed for this are that more efficient drainage is thus secured than is possible from an anterior opening; that the edges of the uterine wound are steadied by its weight and position; that the greater thickness of the posterior wall will help to prevent gaping of the wound, etc.

But, in spite of all this and much more, the practical difficulty of managing the incision, and the liability of finding the placental attachment there as well as in front, have so far deterred operative surgeons from attempting it; nor is it likely ever to win favor.

In all cases of Cæsarean section, Harris ("International Enclycopædia of Surgery," vi., 770) thinks the most fatal mistake is *delay*, and the chief desideratum for the future is more perfect knowledge of pelvic deformity among practitioners who attend the poor in large cities; if this were recognized early in the case, and an experienced consultant called in, many lives now lost could be saved. To lessen the mortality from this cause, certain substitutes for Cæsarean section have been proposed, of which the chief are:

I. The Porro or Porro-Müller operation, with Veit's modification.

II. Laparo-elytrotomy by Thomas' method.

I. The first of these was devised by Professor Edoardo Porro, of the Maternity Hospital of Milan, formerly of Pavia, who in May, 1876, operated successfully on a rachitic primipara, aged twenty-five. He termed the process "utero-ovarian amputation, as completive of Cæsarean section;" and its special object was the diminution of former mortality "by converting the internal uterine wound, with its tendency to gape and discharge septic matters into the abdominal cavity, into one dressed and discharging *without* the peritoneal cavity" (Harris, loc. cit., p. 770).

Dr. H. R. Storer had done the same thing in 1869, but without premeditation, during an ovariotomy, when the tumor proved an uterine fibro-cyst associated with pregnancy.

And the *idea* had long before been expressed by Cavallini, of Florence, in 1768; by Michaelis, of Marburg, in 1809; by Dr. Blundell, of London, in 1828; and by Fogliata, a veterinary surgeon of Pisa, in 1874.

Whether Porro knew of the earlier suggestions is doubtful; of Fogliata's he was ignorant.

All his predecessors had recommended the *entire* ablation of the womb; he excised it at the cervix, and drew the stump into the abdominal wound.

His method, then, is precisely that of the modern antiseptic Cæsarean section, *plus* hysterectomy at the cervix with external treatment of the pedicle.

After the uterus had been incised and evacuated, it was drawn out of the abdomen and held vertically while the wire loop of Cintrat's constrictor was tightened around the cervix, opposite the internal os, and the uterus cut away above it. The abdominal cavity was then cleansed, and a drainage-tube carried through the abdominal wound, through Douglas' pouch, and out of the vagina. The external wound was closed with silver wire, the stump fixed in its lower angle and rubbed with perchloride of iron. Antiseptic dressings were applied; the wire loop was removed in five days, the woman was well in forty, and the child was saved.

Several modifications of this proceeding have been offered; two only demand notice here.

a. The first, by Professor Müller, of Bern, after eight operations had been done by Porro's method, consisted in turning the pregnant womb out of the abdomen *before* opening it and evacuating its contents. This was to avert the danger of hemorrhage, and the escape of its possibly putrid contents into the peritoneal cavity. Otherwise it is the same as Porro's.

b. The second, by Professor G. Veit, of Bonn, consists in ligating the stump and dropping it back into the peritoneal cavity, or treating it by the *intra-peritoneal* method. This ligation has been done with silk and with silver wire, and with and without peritoneal covering.

Neither of these modifications has been followed by sufficient success to justify the hope that it will supplant the original operation of Porro.

Up to this time Veit's has shown a general mortality of nearly seventy-one and one-half per cent.

Müller's has been entirely unsuccessful in Italy, but less so elsewhere.

Dr. Harris (op. cit., p. 773) says that up to March, 1885, there had been 42 operations by the Müller modification, with 21 mothers and 31 children saved; by the original Porro method 109 operations, saving 46 mothers and 85 children.

These statistics may, of course, soon be modified.

II. Of the second substitute for Cæsarean section, laparo-elytrotomy, it would seem that little need be said in this Academy, which witnessed and welcomed its chief public exposition by its distinguished author. If he had done nothing else in the specialty which he has illuminated with his talent, this alone would entitle him to our lasting gratitude; for such ingenuity, boldness, sound anatomical knowledge, and far-reaching intelligence have rarely been combined in any surgical proposal.

The special object and merit of this proposition are the extra-peritoneal extraction of the child above the pelvic brim, without wounding either the uterus or the peritoneum; and, consequently, without risking the mortality which has hitherto followed those lesions.

As seems curiously true of many other notable discoveries, this had all been discovered before; but neither Ritgen, who first attempted it sixty-five years ago; nor the younger Baudelocque, who, two years later, proposed the same expedient, and actually operated in two cases, which were afterward forgotten; nor Sir Charles Bell, who, thirty years since, theoretically advised the same procedure, can jeopardize the just claim of Thomas to originality. For, while their efforts were either incom-

plete or soon forgotten by even the few who [illegible] gained, Dr. Thomas, who was unaware of their labors, had the energy to push his new discovery to a practical conclusion, and to bring it before the profession so forcibly that it has permanently taken its place in obstetric literature.

Needless to describe it in detail to you at this late day, for you are all as familiar with it as I am; and, since the classical essay of Garrigues upon this subject in 1878, it has been incorporated into all recent treatises upon operative midwifery. As to its results, I need only add that Skene and Jewett in Brooklyn, Gillette and Thomas himself in this city, Hinds and Edes in England, have all had successful cases; and, although the number is as yet too small for any final deduction, the proportionate success is for greater than that of either Porro's operation or Cæsarean section.

Has surgery rendered aught of assistance in extra uterine pregnancy? Some of its greatest triumphs have been won in this field, and each year brings gratifying evidence of improvement in the methods and technique of such operations.

In the early months—before the fifth month—of ectopic gestation, electricity, which was first employed by Allen, of Philadelphia, and popularized chiefly by the writings of Thomas and Garrigues, is preferred in this country to the use of the knife.

After that period incision, or excision, should be attempted, either by elytrotomy, laparo-cystotomy, or laparo-cystectomy.

1. In puerperal elytrotomy the upper segment of the vagina is incised so as to reach and remove a fœtus in the lower pelvis. This is generally enclosed within the layers of the broad ligament, and has originally been a tubal pregnancy. The operation is rather difficult and fraught with much risk, especially if an attempt be made to tear away the placenta, when profuse hemorrhage ensues.

It has been done in this country, with varying success, by Dr. John King, of South Carolina, in 1816; by Hayes Agnew and A. H. Smith, of Philadelphia; by Thomas, of New York, and by Dr. Mathiesen, of Ontario, Canada. Thomas advises that the vagina be divided by the galvano-caustic knife, to avoid the danger of hemorrhage.

It is rarely applicable in practice.

2. Puerperal laparo-cystotomy is the process of opening the abdomen and the enveloping cyst for the purpose of extracting the enclosed fœtus. This may be done either to remove a *living* fœtus, or after the fœtus is known to be dead; and the operations are respectively called *primary* and *secondary*.

The procedure is not of modern date, Harris quoting one by Christopher Bain, a German, in 1540; and by Paul Calvo, of France, in 1714. Both of these were *secondary* operations.

Professor R. Werth, of Kiel, tabulated, in 1884, 17 primary operations, with 2 recoveries and 15 deaths.

These two were at the eighth month of gestation, and were done by Jessop, of Leeds, in 1875, and by A. Martin, of Berlin, in 1881. A full report of the details of these remarkable cases will be found in Dr. Harris' erudite article in the "International Encyclopædia of Surgery," vol. vi., p. 783.

The cause of the great mortality in most of these cases was the location of the placenta and the difficulty of dealing with it.

Even an explorative incision, as recommended by Tait, is full of risk, as we may cut into the placenta or fail to find its location until we are compelled to remove the fœtus.

Any one of the three main forms of ectopic gestation—the abdominal, ovarian, or fallopian—may give rise to this indication.

3. Laparo-cystectomy is practically the same as the foregoing, except that the enveloping cyst is removed with the fœtus.

If this can be done at all, it is easier and safer than the preceding measure; because here the placenta is encapsulated with the fœtus, and, in the complete ablation of the sac or cyst, the risk of placental hemorrhage is avoided.

Of *lacerations* of the *cervix* and of the *perineum*, and of their immediate repair, so much has been written that I shall make only the most passing reference to this subject.

I have never been so fortunate as to succeed in closing a lacerated cervix at the time of labor, though I have made a number of efforts in that direction; nor have I known of more than one surgeon who claims to have accomplished this. But, with our constantly improving appliances and resources, that this *will* be accomplished in the early future I firmly believe.

With *lacerations* of the *perineum*, however extensive they be, and whether complete or incomplete, the case is very different. Here the advantages of immediate closure are so immense in saving the unfortunate patient from the discomforts of prolapse, and the greater misery of *procidentia of the womb*, that the obstetrician is derelict in his duty who fails to avert this by immediately repairing the perineal tear if the latter be at all extensive.

Were this systematically done, it is no exaggeration to say that hundreds of young mothers who lead invalid and useless lives at home, or who fill the gynecologist's consulting rooms, would be restored at once to their family duties. So imperative does this duty seem to me that I would as soon think of leaving the placenta undelivered in the uterus as a deeply torn perineum unrepaired.

Much more might be said upon so suggestive a theme, but the proper limits of this paper have already been passed.

Suffice it, then, to say, in conclusion, that if the application of surgical resources to obstetrics in the ten or twenty years just past has been so beneficent, saving, as it has surely saved, the lives of hundreds of women and children who, but for such aid, would long since have been in their graves, we have no cause to fear that the future will be less productive of good. The hand upon the dial of time never moves backward. And so firm is the foothold obstetric surgery has now obtained that one need be no optimist to believe its future outcome will be more brilliant than any of its past achievements.

THE DIAGNOSIS OF ASTIGMATISM WITH THE OPHTHALMOSCOPE.

BY FRANCIS VALK, M.D.,

[illegible]

THE diagnosis and determination of astigmatism with the ophthalmoscope, by the direct method, is not only exceedingly interesting, but somewhat difficult, unless we estimate each meridian of the two principal ones separately, then it should become almost as easy as the diagnosis of simple hypermetropia or myopia, when we have simply an elongation or shortening of the optic axis, except in those few cases in which the refractive power of the dioptric system may be either too strong or too weak.

But if one has mastered the use of the ophthalmoscope in the simple errors of refraction the same rules will hold good in the diagnosis of the curvature of the cornea, which causes astigmatism, only we must now select the two principal meridians of the eye, finding them at right angles to each other. This will give us the direction of the axis of the correcting cylindric glass, and then we can estimate the amount of error of refraction in each meridian, in the same way that we would test the eye for simple hyperopia or myopia.

In determining the simple errors of refraction we take as our standard of comparison the minute vessels of the disk or retina, or, better still, the delicate tapetum formed

by the choroidal epithelium, and then, in hypermetropia, use the strongest convex glass behind the aperture of the ophthalmoscope with which this tapetum can still be distinctly seen, this will give the amount of hypermetropia, while in myopia we would select the weakest concave glass that will render the blurred tapetum distinct, and this glass will give us the amount of myopia.

Now, in astigmatism, we cannot use this delicate test, so we select the edges of the optic nerve entrance, which, passing in a circle, will give us short lines running in any direction, or the minute delicate vessels that you will find in different parts of the retina or on and around the optic disk, while the most delicate test is that of the brilliant white line running along the centre of each artery of the retina. If we take any of these points for observation, and can decide which will focus upon the retina of the observer's eye, these vessels or lines will give us the direction of the meridian of greatest ametropia, provided in all cases that the accommodation of the observer is in a state of complete relaxation.

We will precede the study of the errors of refraction caused by astigmatism by the supposition that very few are able to have such complete control over their accommodation that they can at all times completely relax it, so that the observer's eye when estimating refraction shall be in a state of complete rest. Now this defect will make but slight difference in estimating myopia, as the observer's eye cannot accommodate for convergent rays, but in hypermetropia it must be taken into consideration, although the practical results should be the same. For instance, very few persons that are accustomed to use the ophthalmoscope can so control the accommodation that they can examine the fundus of a hypermetropic eye of + 1 or 2 D. and find the details blurred and indistinct. But making our diagnosis from the fact that we can still see these details clearly, by placing a convex glass behind the aperture, and the strongest convex represents the amount of total hypermetropia, so we must calculate the amount of astigmatism present, if hypermetropic, only using the individual vessels as our guide.

I shall not quote the writings of our many standard authors, as it has seemed to me that nearly all of them dismiss this most important subject, and one that is so necessary to the ophthalmologist, with very few words; even our most illustrious master on refraction, Donders, says almost nothing, while Dr. E. G. Loring, in his excellent work, lately issued, on ophthalmoscopy, devotes hardly five pages to this subject, though his explanations are unquestionably the best and clearest that it has been my pleasure to read.

If we could so control the accommodation that, when using the ophthalmoscope, one eye would be in a state of complete rest, as when under the influence of a strong solution of atropine, then I can understand and appreciate the teaching upon this subject; but if we consider that with a large majority of those who use the ophthalmoscope the accommodation is particularly active when examining a hypermetropic eye, we must then study and calculate the errors of astigmatism in a somewhat different manner.

In teaching the determination of astigmatism we must only consider those rays of light that are reflected by the retina of the observed eye, after proper illumination with the ophthalmoscope. In doing so we must estimate separately the refraction of the two principal meridians at right angles to each other, the direction in which the rays of light of each meridian leave the cornea, and the direction that they will have when they strike the retina of the observer's eye, after they have passed through the dioptric media of both eyes.

This has been beautifully shown by my friend and assistant Dr. W. H. Fox, at our clinics, and at his lectures at the Post-Graduate Medical College. We have used small disks of cardboard to represent the refractive apparatus of the observed and the observer's eye, while small threads of different colors, placed in different planes, represent the rays of light in the two principal meridians.

By this method, if we take the rays of light from any luminous spot in the retina passing through the dioptric media of the observed eye and then through that of the observer, their directions and focal points will be the same as parallel rays of light passing through a spherical and a cylindrical lens combined, so that we will find beyond the refractive media of the observer's eye the two principal focal points, with the focal interval of Sturm between them, that in hypermetropic astigmatism the retina of the observer's eye lies at the anterior focal point, and that in myopic astigmatism the retina of the observer's eye lies at the posterior focal point. Also in compound astigmatism the retina is in front of the anterior focal point in hypermetropia, and is behind the posterior focal point in myopia, while in mixed astigmatism the retina lies between the anterior and posterior focal points.

Now, in all these cases, but particularly that of simple astigmatism, which I shall take as a standard, we will find that the image, as formed upon the retina of the observer's eye, is elongated in the meridian of greatest ametropia, consequently all vessels or lines that pass in the direction of this meridian will be clearly seen, *provided the accommodation is at rest*, because the rays that define the edges of these vessels will pass outward through the emmetropic meridian, and will leave the eye as parallel; while all the rays that pass outward in the meridian of ametropia, when they strike the retina of the observer's eye, will simply overlap, so forming a clear, elongated image, but in hypermetropic astigmatism the student will *almost invariably use his accommodation*, and now he will see the vessels in the emmetrophic meridian, as the rays will focus upon his retina at the *posterior focal point*, exactly at right angles to the vessels parallel to the meridian of ametropia.

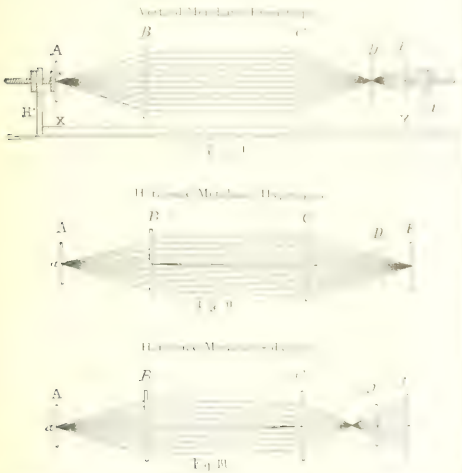
By looking at the drawings you will see in Fig. 1 the stand represented, with one set of cardboards and threads in position, showing the direction of rays of light in the vertical meridian, while in Figs. 2 and 3 the cardboards and threads only are represented, but are so made that they can be easily attached to the stand by a slot, and then tightened up by the nuts on the screws at the ends. These figures are reduced about one-sixth the actual size, and this method can be used to illustrate all the varieties of refraction and astigmatism.

Explanation: In Fig. 1, let X, Y, represent the stand, with two uprights, H and I, on each end, through which the screws pass, with a small movable nut on each screw, by which the threads are tightened after the cardboards are in position, then the cardboard at A will represent the retina of the observed eye, and *a* the luminous point, B the refractive apparatus, while C will represent the refractive apparatus of the observer's eye, D the position of the retina, and E the position of the posterior focal point in simple hypermetropic astigmatism. By placing these cardboards in the stand, with the rays of the two principal meridians shown by different colored threads, they can be turned to any meridians in the arc of a circle, though in the drawings they are only shown in the vertical and horizontal; then if you combine Figs. 1 and 2, or Figs. 1 and 3, you will see that in no case can the rays from the luminous point *a* form a point upon the retina of the observed eye, but must be elongated in the direction of curvature different from that of emmetropia.

In Fig. 3, representing the horizontal meridian of an astigmatic eye whose refraction is myopic, we find the rays of light in this meridian or plane to pass outward convergent; consequently, they will cross before they strike the retina of the observer's eye at D, and then form an elongated image; as the rays passing outward in the other principal meridian will be parallel, as shown in Fig. 1, they will exactly focus upon the retina at D, and as these rays in this meridian form the boundary lines of the vessels in the opposite meridian, then in this case the vessels

that pass horizontally will be clearly seen; that being the meridian of greatest ametropia, the axis of the correcting cylindric glass must be placed at right angles to it, or, in other words, at right angles to the vessels that are distinct.

If we now study the direction of the rays passing from a hypermetropic eye, under the same conditions, we shall find that they also form an elongated image upon the observer's retina, in the same meridian of ametropia, but now the image is formed by the rays in the horizontal meridian, reaching the retina at D before they have come to a focus, as shown in Fig. 2, while the rays passing in the vertical plane, Fig. 1, are parallel, and exactly focus upon the retina of the observer's eye.



Diagrams of [illegible] and the [illegible] simple hypermetropic [illegible]

Now, if the observer is able to keep his accommodation *completely relaxed*, this proposition is correct, and he can only see the vessels that pass in the horizontal direction; but as so few of us, particularly those who are learning to estimate refraction, can keep the accommodation at rest when divergent rays pass in the eyes, hence, using the accommodation we will focus all the rays upon the retina, and all the vessels are now clear. If we then place a convex glass behind the aperture of the ophthalmoscope, which takes the place of and relieves the accommodation, we now change the rays of light as if they came from an eye with simple myopic astigmatism, as the convex glass will focus the divergent rays in the horizontal meridian upon the retina, at the same time will bend the parallel rays in the vertical meridian, and they will then focus before they reach the retina of the observer's eye, so that the position of the retina is now changed to the posterior focal point, and the vertical vessels can be seen, most distinct, exactly at right angles to the vessels seen with the accommodation relaxed, consequently the axis of the correcting cylindric glass must be placed *parallel* to the vessels, most distinctly seen in hypermetropic astigmatism when the accommodation or a convex glass is used, and the strongest convex glass, with which these vessels are clear, will represent the amount of ametropia.

These same rules will apply in compound astigmatism, but we must first correct the general refraction in myopia by the weakest concave glass that will make the vessels in any one meridian distinct, and in hypermetropia by the strongest convex glass that will first blur the vessels in any meridian.

We can illustrate these rules by the following cases: In simple myopic astigmatism the vertical vessels are distinctly seen through the aperture of the ophthalmoscope, then with -2 D all the vessels are clearly seen, as the accommodation will correct the divergence of the parallel rays caused by the concave glass, hence the correcting cylindric glass would be -2 D.c, axis 180°, or horizontal.

In simple hypermetropic astigmatism, all the vessels can be seen in every meridian, but if we place a convex glass behind the aperture, as $+2$ D, the vertical vessels can still be distinctly seen, while all the horizontal vessels are blurred, we now find that the correcting cylindric glass will be $+2$ D.c, axis 90°, or vertical, the axis now being parallel to the vessels most distinctly seen.

Let us now take a case of compound myopic astigmatism. All the vessels will appear blurred, and the weakest concave glass that will make the vessels in any meridian clear, say -2 D, will show these vertical vessels; then we have general myopia of -2 D, and the axis of astigmatic glass must be at *right angles* to the vessels; then we will measure the amount of astigmatism by the weakest glass that will make all the vessels clear, as -4 D, and the difference between these two glasses will give the amount of astigmatism. Thus, the proper glass to correct this case would be -2 D.s $\bigcirc -2$ D.c, axis 180°, or horizontal.

But in a case of compound hypermetropic astigmatism all the vessels can be clearly seen, as the accommodation will be active, and now the strongest convex glass that will first blur the vessels in any meridian, as with $+2$ D the vessels in the horizontal meridian begin to blur, this glass will represent the amount of general hypermetropia, and now the axis of the astigmatic glass must be *parallel* with the vessels that are *still* distinctly seen, then the strongest convex glass that these vessels in the vertical meridian can be seen with, as $+4$ D less the amount of general hypermetropia, will represent the astigmatism. So the correcting glass would be $+2$ D.s $\bigcirc +2$ D.c, axis 90° or vertical.

In mixed astigmatism with the vertical meridian myopic and the horizontal meridian hypermetropic, you will see the disk elongated in the direction of the myopia, or vertically. All the vessels and lines running vertically are distinct, unless all the accommodation is relaxed, when the vessels and all the details of the fundus will be indistinct. But this condition is difficult to accomplish, and so using the accommodation we can see the vertical vessels clearly; then the strongest convex glass through which they can be seen, as $+2$ D, will represent the amount of hypermetropic astigmatism; now place the axis of the correcting glass parallel to these vessels, and we have $+2$ D.c, axis vertical. The hypermetropic astigmatism being in the horizontal meridian. Let us now place the weakest concave glass, behind the aperture, that will render all the details of the fundus clear, as -2 D, and we have the amount of myopia; placing the axis of the cylindric glass at right angles to the vessels first clearly seen, then the correcting concave cylindric glass will be -2 D.c, axis 180°, or horizontal, with the myopic astigmatism in the vertical meridian. So this case of mixed astigmatism will be corrected by $+2$ D.c, axis 90° $\bigcirc -2$ D.c, axis 180°.

I wish the student to remember that these calculations are only made in this way because most physicians who use the ophthalmoscope are unable to control the action of the accommodation; while if we do have perfect control at all times, then we can only see the vessels distinctly that are parallel to the meridian of greatest ametropia, and consequently the axis of the correcting cylindric glass must be at right angles to that meridian.

I have been led to these conclusions from actual experience in the examination of a large number of cases of astigmatism, without the use of atropine, and have confirmed the diagnosis afterward with atropine and the trial by glasses. Again, so little is written on this interesting subject, while I could give so many examples from my records, while on service at the Manhattan Eye and Ear Hospital, that have been studied and the diagnosis made

by this method; at the same time, I know from personal experience that it was very difficult to so master my own accommodation as to obtain the results given in our text-books. Nor can I speak too highly of the ability to make a correct diagnosis of all the errors of astigmatism, as in many cases it will enable us to decide if it is necessary to continue the examination under the use of atropia, as well as showing the cause of the apparent amblyopia.

I would therefore conclude:

That the direction of the axis of the correcting cylindric glass in myopic astigmatism is at *right angles* to the vessels that are most distinctly seen without a glass.

That the direction of the axis of the correcting cylindric glass in hypermetropic astigmatism is *parallel* to the vessels that are most distinctly seen with a glass.

That the same rules are applicable in compound astigmatism, only we must correct the general error of refraction first, and then the astigmatism.

Lastly, that these rules are presented, from the fact, as I believe, that the largest number of those who use the ophthalmoscope cannot control their accommodation at all times, when divergent rays of light enter the observer's eye.

Progress of Medical Science.

Nerve Terminations in the Pepsin Glands of the Stomach.—Fragments of the stomach, taken from a fasting dog, and treated by bichromate of ammonia in five per cent. solution, show the parietal cells containing, besides the nucleus, from one to five homogeneous granules stained of a yellow color. Langley has described these as pepsinogenous bodies, but Navalishin (*Archives Slaves de Biologie*, No. 1, 1886) regards them as the terminal organs of the nerve-fibres. In a section of the mucous membrane treated by bichromate of ammonia and then by chloride of gold, he has seen a filament passing from a nerve-branch enter the capsule of the gland, penetrate a parietal cell, and terminate in one of these granules in its interior.

How the Mussel Opens its Shell.—Dr. J. Pawlow has been studying the action of the adductor muscles of the valves of the fresh-water mussel (*Anodonta cygnea*), and has obtained results of considerable interest in the physiology of muscles and nerves. The following are the conclusions of his paper: The two adductor muscles receive each two sets of nerve-filaments, one motor and regulating the contraction or shortening of the muscle, the other antagonistic to the first. The latter might be denominated arrestors, since their action is to suspend the contraction of the muscle and induce relaxation in it. These two sets of nerves have, in respect to the adductor muscle, a rôle analogous to that of the vaso-constrictors and vaso-dilators in respect to the muscular coat of the arteries in the higher animals.—*Revue des Sciences Médicales*, April 15, 1886.

Atrophy of the Superior Maxilla.—Dr. Dubreuil reports the case of a man, thirty-three years of age, who had begun to lose his teeth about a year previously. There was no pain, and the teeth simply became loose and fell out during mastication or were removed by the fingers. None of the teeth was carious. The molars began to fall out first, and at the end of six months there was not a single tooth in the upper jaw, but throughout there had not been the slightest pain. After the disappearance of the teeth the alveolar border became thinned, ulcers were formed, then hemorrhages followed from the nostrils, and from time to time little pieces of bone, with mucous membrane attached, were removed from the nasal fossæ. There were flying pains at this time in the lower extremities, most marked at night. At the time of the patient's admission to hospital the vault of the palate was of a triangular shape, presenting a cicatricial appearance at the sides, and a fistula communicated on the left side with the nasal fossa. On the right side a small ulceration existed at a point from which a little spiculum of bone had been removed. The patient died with symptoms of cardiac affection. At the autopsy were found ulcerative endocarditis, passive congestions, and general anasarca. The brain was small, the frontal lobes especially appearing to be but little developed. The meninges of the cord, particularly the dura mater, were thickened posteriorly. The medullary lesion was situated in the sinus formed by the separation of the posterior cornua. The sclerosis was diffuse, and was especially marked at the extremity of the right posterior cornu, where the abundant connective-tissue fibres had destroyed the nervous filaments. The changes appeared to be more marked toward the cervical region and to decrease and finally disappear in the dorsal portion of the cord. The bulb, the superior maxillary ganglia, and the nerves themselves could not be examined. The lesion in the bone was simply that of necrosis. Whether there was any relation between the cord lesion and the atrophy, M. Dubreuil was not prepared to affirm.—*Revue des Sciences Médicales*, April 15, 1886.

Pulmonary Œdema.—In 1878 Welch advanced a theory, founded upon certain experiments, of pulmonary œdema according to which the condition was due to left cardiac insufficiency; the right ventricle continuing to contract with force, a stasis of the blood within the lungs occurred. Sahli has recently repeated these experiments and performed others, from a study of the results of which he draws the following conclusions (*Archiv für Exper. Path. und Pharmak.*, No. 6, vol. 19): 1. Pulmonary œdema is never produced in the manner described by Welch. 2. In the majority of cases the affection is not due to stasis of the blood, but is similar to nephritic or cachectic œdema. 3. In sufferers from heart-disease there arises sometimes, though rarely, an œdema from blood stasis due to regurgitation from the left ventricle. 4. Phlebotomy is a therapeutic measure, as efficacious as it is rational, in the treatment of œdema from blood stasis, and it would probably be of equal value in other forms of pulmonary œdema. 5. The operation of transfusion of blood is contraindicated in œdema of the lungs or when circulatory troubles threaten.

A Modified Pirogoff's Operation.—At the recent congress of Russian practitioners, Professor Tauber described and demonstrated on the dead subject an operation for removal of the foot, which he believes has several advantages over Pirogoff's amputation. Standing on the outer side of the limb, he commences an incision at the insertion of the tendo Achillis, and carries it forward just below the external malleolus to the dorsum of the foot, and then vertically downward on the inner side in front of the heel. When the middle line of the sole is reached, the incision is carried along it backward and prolonged upward to the starting-point at the insertion of the tendo Achillis, a flap having thus been cut consisting of the inner side and half the sole of the heel. The joint is then opened, the external ligaments being first divided and then the internal. The astragalus is seized with the bone forceps and removed, and the anterior part of the foot cut off by Chopart's line, nothing being left but the os calcis, the soft coverings of which on the inner aspect are untouched. The os calcis is seized with the bone forceps and turned so that the articular surface is toward the operator. The forceps are now taken by an assistant, who holds them tightly; the operator then saws the bone longitudinally in two; the outer half, which is free, is removed, the inner half remaining attached to the flap. The ends of the tibia and fibula are then sawn off just above the malleoli. The cut surfaces of these will be found to correspond almost exactly with that of the os calcis, which is not brought into apposition with them. The advantages claimed for this operation are: 1. The posterior tibial artery itself is untouched, only its

branches being divided. 2. The insertion of the tendo Achillis, as well as its bursa, are not injured. 3. The surfaces of the os calcis and of the leg bones correspond very nearly to one another.—*The Lancet.*

Some Curious Dislocations.—Mr. H. Addison writes in *The Lancet* of April 3, 1886, that he was witness of an accident, happening opposite his house, which resulted in a curious dislocation of the third cuneiform bone. A man was endeavoring to mount a barebacked horse, which was standing close to the curbstone. He threw his right leg over the animal, which started forward with a bound, dislodging him backward. As the horse passed from under him, he came down upon the edge of the curbstone with his left foot flexed and abducted. The sole was also somewhat everted. The patient, a man of about thirty-five years, of pale and relaxed fibre, showed upon examination a dislocation of the external cuneiform bone. The luxation was somewhat peculiar; the entire bone, being displaced upward, lay upon the inner edge and dorsum of the os cuboides. About half the dorsal surface of the cuboid bone was covered by the plantar surface of the cuneiform. The displaced bone could be very distinctly seen through the stretched skin of the dorsum of the foot, as if a cube had been placed under it. The patient suffered very little pain, and the bone could be easily reduced by mere pressure upon the dorsal surface, with only the slightest possible extension of the toes. When the foot was flexed by the will of the patient the luxation recurred. The member was placed in an appropriate splint, with a graduated pad over the displaced bone. The man was then removed to his home, some miles away. He thus passed from Mr. Addison's care, and nothing further was heard from him. Dr. H. A. Hallett reports in the *British Medical Journal* of May 8, 1886, the case of a laborer who came to him saying that he had fallen off a tree, and that a branch he had been lopping had fallen on and hurt his wrist. On examination a conical protrusion was found on the back of the right hand, which proved to be the carpal end of the metacarpal bone of the middle finger, entirely dislocated. The deformity was soon reduced by traction and manipulation; but, on the slightest movement of the hand, the bone became again partially dislocated, and kept rising up as soon as replaced, being only kept in position by pressure. The hand was extended on a splint, and a pad and bandage applied.

Genital Manifestations of Malaria.—M. Girard has observed in Turkey, Italy, and America various affections of the genital organs which he believed to be of malarial origin. He based his diagnosis of malaria in these cases not only on the enlarged spleen, intermittent febrile paroxysms, cachectic hue of the skin, etc., but also upon the results of a microscopical examination of the blood. He describes, as dependent upon paludal infection, orchialgia, neuralgic orchitis, epididymitis, and urethritis. He has observed, also, an ordinary gonorrhœal orchitis in which the symptoms were paroxysmal in character, the pain being intermittent, and specific urethritis, in which the discharge was intermittent and coincided in time with well-marked malarial paroxysms of fever, etc., disappearing as these attacks passed off.—*La Crónica Médica*, May 5, 1886.

Treatment of Catarrhal Icterus by Enemata.—Lowenthal states that he has seen remarkable success follow the use of rectal injections in the treatment of catarrhal jaundice. The following is the method as practised by Professor Meyer, of Vienna. The first day from two to four pints of water at a temperature of from 53° to 55° F. are injected; the second day the same quantity is employed, but the temperature is raised to 58° or 60° F.; on the third day water at 65° F. is used, and on the fourth day the temperature is raised still further, to 75° F. Usually this is sufficient to effect a cure, but if not, the injections are continued, the water being warmed a few degrees more each day. For children the quantity of fluid should not exceed a pint and a half, but in the case of adults from three to four pints may be used. The dejections are at first of a clay color, but by the third day they become yellow. The epigastric pain and feeling of weight over the hepatic region are relieved usually by the first injection, and the appetite quickly returns, and the icterus fades. The writer states that he has seen this mode of treatment employed in over forty cases, always with success.—*Gazzetta Medica di Roma*, May 1, 1886.

A Large Biliary Calculus.—The following case is related by Dr. Roeser in the *Gazette de Gynécologie* for May, 1886: "The patient was a woman, sixty-five years of age, somewhat obese, but of fair general health. She had previously had one or two attacks of hepatic colic, the last one of which was rather severe and accompanied by vomiting and slight jaundice. Some three weeks later she noticed, while at stool, that some hard body obstructed the passage, preventing defecation. This was removed by the finger introduced into the rectum, and was found on examination to be a biliary calculus. It had a flattened ovoid shape, and measured an inch and a half in its longest diameter and one inch in its shortest. On being broken its central portion was found to consist of a granular friable matter, dark in color, and somewhat resembling snuff. This suggested dried blood, but examination showed it to be composed of bile pigments and earthy carbonates, no trace of blood being found on microscopical or spectroscopical examination.

A Classical Remedy for Hiccough.—Dr. A. G. Gibson calls attention to the old Hippocratic aphorism, "Sneezing occurring after hiccough removes the hiccough," and suggests, in cases of hiccough, the production of sneezing by tickling the nostrils, and he tells us that he has in this way been very successful in the arresting of this disagreeable affection. Hiccough, as well as sneezing, is one of the specially modified respiratory movements, and it is quite in accordance with what we know of the transference of nervous action that the spasmodic contractions of the diaphragm should cease on the induction of the explosive expirations which constitute the acts of sneezing. There is one point, however, which deserves special mention. It is not necessary that the stimulus applied to the nose be followed by sneezing. The application of a gentle irritant to the nasal mucous membrane may be quite enough to put a stop to the hiccough, by diverting the nervous energy into other channels, although it may not be of sufficient power to induce sneezing.—*The Lancet and Clinic.*

Headache in School Children.—Professor N. J. Bystroff has examined 7,478 boys and girls, in the St. Petersburg schools, during the last five years, and found headache in 868; that is, in 11.6 per cent. He states that the percentage of headache increases almost in a direct progression with the age of the children, as well as with the number of hours occupied by them for mental labor; thus, while headache occurred in only five per cent. of the children aged eight, it attacked from twenty-eight to forty per cent. of the pupils aged from fourteen to eighteen. The author argues that an essential cause of obstinate headache in school children is the excessive mental strain enforced by the present educational programme, which leaves out of consideration the peculiarities of the child's nature and the elementary principles of scientific hygiene. The overstrain brings about an increased irritability of the brain, and consecutive disturbances in the cerebral circulation. Professor Bystroff emphatically insists on the imperative necessity for permanently admitting medical men to conferences of school-boards. Of palliative measures he mentions methodical gymnastics, mild aperients in well-nourished children, steel in the anæmic, bromides, inhalation of oxygen, and, in severe cases, a temporary discontinuance of all studies.—*British Medical Journal*, May 15, 1886.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 12, 1886.

OPPOSITION TO THEORIES OF MICROBIAL INFECTION.

AT the meeting of the Alabama State Medical Association, held in Anniston on the sixteenth of last month, Dr. B. J. Baldwin reported twenty-five successive extractions of cataract without a failure. In the course of his remarks on these cases he said that he had used no disinfectants, and did not consider them necessary outside of hospital walls. He also said that he had been very much interested, and rather amused, at the scrupulous disinfection of the eyelids and eyeballs, and the hysterical anxiety to have even both eyes deluged in solutions of bichloride of mercury and boracic acid preceding every operation. He did not wish to be understood as denying that disinfection might often do good in the poisoned wards of old hospitals, but he did assert that anything more than cleanliness, in the extraction of cataract, outside of the hospital, was unnecessary and sometimes even harmful.

Then speaking of antisepsis in general, he continued: "I do not believe, furthermore, that there exists in all space a deadly venom ready and anxious to leap into every wound, to hasten the part on to destruction. There is bread that hath no leaven, and air as well without germs. Many of my friends may think this unpardonable heterodoxy, and my German confrères will no doubt stand aghast, but I am confident that they will sooner or later come to the conclusion that the world is not so soaked in bacteria as they at present imagine. It is difficult to conceive that an all-wise and ever-merciful Maker would have so filled His universe with these infinitesimal death-worms, and that fresh air and sunshine are simply the danger-house from which they may be signalled when an opportunity to attack a wound arises. Cleanliness embraces all of the virtues of disinfection, and it is the sole element of its success."

These are certainly pretty strong words, but judging from the indications we see about us we may expect now to hear declarations of this sort from many different quarters. The opponents of bacteriological theories are beginning to assert themselves with much more vehemence than they dared to use a short time ago, and, gaining courage as they proceed, they will give the advocates of the new doctrines a task in defending their theories. We are not sorry to see the signs of the approaching tsruggle, for, true or false, the microbial theories have, we think, been too readily accepted by the mass of the profession upon the authority of a few learned investigators. All the arguments pro and con have not yet been set forth as clearly as they might be; and an animated discussion will do good in establishing the truth or falsity of these latest theories of disease. But the conservatives must remember that talk is not always argument. The bacteriologists allege facts and experimental research as the basis upon which their theories rest, and their opponents must bring forward equally strong facts if they wish to gain the approval of the profession for their cause.

A QUESTION OF DIGESTION.

THE doctor is, perhaps, the very last individual to whom a student of social topics turns for advice. Yet he might, at times, learn something even from this source, of which Descartes, at least, has spoken in terms of more than respect.

Modern philosophy has taught us that man, in his fœtal growth, gives us a minute but faithful image of the slow development of animal forms. We learn evolution from embryology. So, also, it has been shown that man, in his post-natal growth and life, is a perfect prototype of the social body. In the development of a united nation one sees the same differentiation of function, the same classes of vital phenomena, and, in a measure, the same disorders as in the individual. It is the old illustration of macrocosm and microcosm, which Goethe understood long before it was elaborated by Herbert Spencer.

It is, we think, sufficiently demonstrated, then, that the doctor who studies the cause of disease in man may suggest something, and that with much confidence, as regards the troubles of man in the mass.

There is to the medical mind little doubt that the United States is now suffering from a condition of indigestion, which has culminated in attacks of *embarras gastrique*. The trouble until lately was a mild one, characterized more by flatulence and anarchical belching than by a serious disturbance of nutrition.

But it appears that we are getting beyond mere flatulence. A man cannot prosper on a steady diet of soleleather and cellulose, neither can the United States quite assimilate a decennial dose of a million and a half of foreigners, mostly of the non-disinfected class.

Smiling philosophers, like Henry Ward Beecher, tell us that this is the land of the free, and that our institutions are strong and noble and sufficient; and so let the foreigner come, whoever he be.

But to the medical philosopher this is not good sense. When a man of magnificent constitution has been steadily gorging himself until he is all blotches and biliousness, we do not say that—the stomach being originally sound, and the constitution naturally substantial—a continuance of the same diet is perfectly safe. Pathology teaches that constitutions do not work up to bad diets, but bad diets gradually undermine the constitution.

And the question now is, whether the United States has a stomach that can manage all the lower classes of Europe.

Our politicians think that it has, because they can manage better newly made voters; our corporations have thought so, because these new voters furnished cheap

labor, but the doctor, with his dietary experiences, feels much doubt. As regards immigrants he would advise a restricted diet, and as regards the anarchical immigrated, perhaps a free purge.

A NEW METHOD OF TREATING WHOOPING-COUGH.

THE parasitic origin of whooping-cough has been asserted and denied by various observers ever since 1867, when Poulet first described what he believed were the specific organisms of the disease. The *a priori* probability that there is a parasite at the bottom of the trouble has led to continued reinvestigations, ending, we are told by Dr. Wm. H. Barlow, in the successful researches of Professor Moncorvo, of Rio Janeiro, in 1883. This gentleman claims to find in the laryngeal and bronchial secretions minute micro-organisms (micrococci), which increase in number with the progress of the disease, and disappear when the patient is cured. No further evidence that these micrococci are pathogenetic is cited by Dr. Barlow, but their discovery was sufficient to induce Moncorvo to institute an anti-parasitic treatment, which he has found very successful, and which Dr. Barlow has adopted with equally good results. Moncorvo reports seventy cases and Barlow fifty thus treated. In Barlow's cases all recovered, and the average duration of the disease was five and one-half weeks. The ordinary duration is generally put down as from eight to ten weeks.

The treatment consists in the application with a brush, every two hours, of a one- or two-per-cent. solution of resorcine. The applications are made to the pharynx and its supra-glottic portion, as well as to the opening of the glottis.

Dr. Barlow gives the following conclusions: "1. That whooping-cough is to be classed among the diseases which are caused by the irritation excited by the presence of parasites. 2. That it is due to the presence of micrococci, which proliferate in large numbers upon the lining membrane of the larynx and pharynx, and which infiltrate the epithelial cells, which seem to be the preferential seat of their growth and increase. 3. That resorcine, in a solution of the strength of one or two per cent., applied directly to the mucous surfaces concerned, has been found, in all cases in which it has been employed and the results watched, to rapidly reduce the number of chinks, to reduce their intensity, and finally to lead to the cure of the disease." This last word "cure" is a bold one, but if the first and second propositions are held to be proven, then there can be little doubt that it is properly used. For if there are no other diseases *cured*, yet certainly those which are due to the irritation of a parasite are cured when that parasite is destroyed.

"Lastly, the mode of application by means of a brush or swab is not the only mode in which it may be made; perhaps by some of the recently used instruments for applying medicated spray to the interior of the larynx and the adjacent parts of the throat (as that recently described by Dr. Miller, of Windsor, and by Dr. Hodgkinson) it may be applied yet more effectually than by the methods adopted by Professor Moncorvo and myself. And, again, it is not finally proven that resorcine is the best application that may be found. Perhaps in its near congener, orcine, we may have a still better agent for this purpose, for we find in a note by J. J. Andeer, in the *Gazetta Medica Italiana-Lombarda* [illegible], that "Orcine possesses almost all the physical properties of resorcine; but while the latter is caustic in large doses, orcine is never more than astringent and antiseptic."

The treatment, as will be seen, though announced as a new one, is in reality only carrying out more systematically the suggestions of previous physicians. Thus, as Dr. Barlow says: "Tordeus has used the benzoate of soda, Keuster, inhalations of thymol; Huebner, salicylate of soda; Hildebrandt, inhalations of petroleum vapor, etc. Resorcine was selected by Moncorvo because of its innocuousness."

The specific treatment of whooping-cough has always run in two lines, viz., toward antispasmodics like the bromides and belladonna, and toward germicides like carbolic acid and resorcine. That we shall be able as a rule to apply germicides so thoroughly as to be specifically effective remains to be seen. It is certain that in antispasmodics and sedatives the best results have so far been obtained, and belladonna and the bromides still hold their place.

A NEW MICROORGANISM OF PHTHISIS.

Two French observers, MM. Duguet and Héricourt, claim to have discovered that the very common fungus, so often seen on the bodies of the phthisical, causing pityriasis versicolor, may itself be a cause of phthisis.

In some cases of acute phthisis the tissues were found to contain no bacilli, but there were observed the mycelia identical with or allied to those of the *microsporon furfur* (the fungus of pityriasis). Similar mycelial threads were also found in the expectoration mixed with the bacilli. When the microsporon furfur is cultivated and injected into guinea-pigs and rabbits, these animals become, without exception, tuberculous, and the same result is obtained by insufflation into the trachea of the crusts of pityriasis. Moreover, the cultures of microsporon furfur, of tubercle produced from the fungus, and those from tubercles of man are precisely the same in character. Cultivations can be made in slightly alkalinized bouillon or in milk, when it becomes possible to distinguish an aërobic and an anaërobic element. The former floats at the surface, and at a temperature of from 30° to 38° C. forms a thick membrane composed of bacilli. The latter is found at the bottom of the cultivation-tube as a mass of granulations and mycelium. The polymorphic character of the tubercle bacillus is thus, says *The Lancet*, manifest, and the opinion of Spina receives support as to the variety of the forms of microbes in tuberculosis.

It seems more probable, however, that the observations of Duguet and Héricourt were not carefully made.

MILITARY DRILL IN THE SCHOOLS.

AN interesting discussion upon the above subject has been awakened by Dr. Charles F. Withington, who read a paper upon it at the recent meeting of the Suffolk District Medical Society. Dr. Withington criticises the drill and intimates that it is an imperfect form of physical exercise, and one which sometimes causes lateral curvature.

His objections as summed up were :

"1. The anatomical objection, based upon the fact of the obliquity of the superincumbent weight with reference to the spinal axis.

"2. The physiological objection, based on the production of a *tension* of the muscles, rather than of that constant alternation of activity and repose which best conduces to their nutrition.

"3. What may be called the philosophical objection, based on a lack of adaptation in design for the end to which the system has become converted."

In the discussion upon his paper a large number of teachers, and military and medical men took part.

All the teachers, with one exception, and all the military authorities favored the drill, not only for its value as a physical exercise, but for its moral effect.

On the other hand, Professor Dudley A. Sargent said that as an exercise it is "thoroughly bad," and sometimes causes asymmetry and lateral curvature. Dr. Bradford, while not recommending it as a perfect exercise, had not seen lateral curvature due to it.

The facts as gathered from the discussion appear to be that the military drill is a very good, though not perfect, means of physical exercise; to say it is "thoroughly bad," or even unsafe, is evidently absurd, provided the drill be carried on with light arms, and ordinary supervision of individuals be exercised. To make up for its deficiency as a gymnastic exercise we have its disciplinary and moral effects, concerning which opinion is unanimous.

On the whole, we should say, continue the military drill in our schools, using arms adapted to the strength of the children, and bearing in mind the occasional bad effects on the development of the trunk and arm muscles.

CHRONIC DIPHTHERIA.

Although diphtheria is usually ranked among the infectious diseases, it is often impossible in individual cases to trace its occurrence to any specific cause, and this is one of the arguments sometimes brought forward by the advocates of "auto-intoxication" against the theories of infection and of the parasitic origin of infectious maladies.

At a recent meeting of the Epidemiological Society of London (*British Medical Journal*, March 6, 1886) Dr. D. Astley Gresswell offered an explanation, which may possibly be a correct one, of these occurrences. He drew attention to the fact that many persons for years after an attack of diphtheria suffer from sore throat, liable to exacerbations, and said that in several instances he could give no satisfactory explanation for an outbreak of diphtheria, unless he admitted the possibility that persons suffering in this way retained diphtheritic infectiveness. He detailed six outbreaks in which the above explanation seemed to him to be the only reasonable one that offered itself. In one instance about thirty or more persons had been taken with, and five of them had died of, diphtheria contracted directly or indirectly from a girl who had suffered from the chronic condition referred to. He also detailed the history of sustained prevalence of diphtheria in a farm-house from March, 1881, to July, 1885 (the latter being the date of his inquiry into the prevalence at the farm-house), and in this a like explanation seemed to be the only one open. Dr. Gresswell dwelt upon the evident bearings which diphtheria in chronic and recrudescent phases had upon sustained prevalence of the disease in a community, and cited analogous instances, such as syphilis, ague, glanders, scarlet fever, and typhoid fever, as tending to support his theory. He suggested that recrudescence of disease, dependent upon a parasitic organism, might prove to be interpretable as due to such rejuvenescence of the parasitic organism as was known to occur among the cryptogamia.

In all the instances in which these cases had been found, the surrounding conditions were such as would be unhesitatingly pronounced unwholesome; and the speaker suggested that persons living under these conditions, instead of entering upon a straightforward recovery, lapsed, so to say, into a chronic condition, the diphtheritic virus leading a smouldering life in the tonsils for weeks and months, and at times (especially when the person had been exposed to wet and cold) entering upon a renewed vitality.

If this explanation be the true one, it only furnishes additional force to the evident necessity of attending to the sanitary conditions of our dwellings, and furthermore, of not dismissing a patient after diphtheria until the chronic tonsillar trouble sometimes remaining is definitely cured.

THE REVIVAL OF A FOLLY.

It is as true of fashion as of history that it repeats itself. It is not so many years ago that every argument of reason and of ridicule was brought to bear against those silly women who thought that by reducing their poor waists to a span they were making themselves more shapely. They finally did abandon the habit of tight-lacing, and doubtless some clever and well-meaning, but evidently rather weak-minded, physicians really thought that they themselves had, by voice or pen, aided in bringing about this happy change. But they had nothing to do with it; fashion did it. And now, we regret to say, fashion seems to have repented, and to be bent on undoing one of her few good works. One can almost see the women's waists grow smaller, and their hideous deformity grow greater, from day to day. And yet the orthopædists are dumb.

If we thought it were any use to sermonize we might detail anew all the evil consequences to health surely following upon such cruel distortion of the body. But it would be a thankless and a fruitless task. Women will have their own way, and no amount of reasoning can tear them from their allegiance to their dressmakers. One might as well try to convince the Chinese that they do wrong in distorting the feet of their female infants, as to turn a fashionable woman from any folly when fashion dictates it. We therefore refrain from argument or reproach, and merely perform the sorrowful duty, imposed upon us as a chronicler of events, of recording the fact that tight-lacing is once more coming into vogue. We can but pray that the epidemic may be short-lived, and that our weak sisters may speedily be delivered from their dire affliction.

DEATH OF ANOTHER OF PASTEUR'S PATIENTS.

THE cable brings the news of another death from rabies of a patient who had been inoculated by Pasteur. The victim was a Roumanian who had been bitten by a mad dog on May 11th, and who was put under treatment on May 25th, fourteen days later. He had been under treatment for eleven days when, on June 5th, he began to show evidences of rabies, and died with the symptoms well marked on June 7th.

It is difficult to see how this case can be explained; and the most that Pasteur can claim now is that after inoculation the ratio of deaths is lessened, as he would claim, from 16 to 0.2 per hundred. Less indulgent critics, who believe that the deaths from wolf rabies should also be counted, would place the ratio at 0.7 per cent., for Pasteur has now actually inoculated about one thousand persons, of whom seven have died. It is very true that 0.7 per cent. is a low mortality rate, but it has unfortunately yet to be determined how many of the inoculated were really bitten by mad dogs.

It is not in the least probable that the Roumanian whose death occurred while under treatment was really inoculated with the disease, although that view will no doubt be suggested. We think that it must be conceded that Pasteur's inoculations are at least harmless.

"THE DANGERS OF KISSING."

THE custom of kissing has been condemned by the wise and frowned upon by the religious, but has managed to thrive despite it all, and is still love's great artillery and best ally. Why tactile sensations from a limited labial surface have been found so very agreeable, and why they should have contributed so much to the poetry and pairing off of the human race are questions quite worthy of full discussion. Kissing, we are told, began with the birds, and reaches its most perfect evolution in man. It has a long history, therefore, and may well be considered a permanent feature in human society—solacing grief, increasing joys, promoting wedding engagements, and furnishing a permanent source of inspiration for the artist.

But an enemy to the kiss has appeared in Washington, D. C., in the person of Dr. Samuel S. Adams, who devotes seven columns of the *Journal of the American Medical Association* to exposing the "dangers of kissing." Everything has its dark side; and so, no doubt, has kissing, especially in Washington, where Dr. Adams lives and where one-half the population is African. If Dr. Adams has painted its dangers in somewhat lurid colors, it may have been thought quite necessary in order to put any check upon so popular a social custom.

The objections to kissing set forth by Dr. Adams are twofold—moral and physical. Kissing, he thinks, has become too common. Among women and between children and adults it has degenerated into an insincere, unmeaning, and commonplace salutation, when it should be reserved only as an index of affectionate feeling. But the weight of the doctor's argument is expended in showing the possible evils which come from the promiscuous kissing of babies and children by adults. Syphilis, tuberculosis, diphtheria, infectious fevers, herpes, eczema, stomatitis, cancrum oris, mechanical distortions of the mouth, injury of the eyes, rupture of the tympanum—all are possible on actual results of kissing. A veritable instance is cited, in which the drum of the ear was ruptured by a kiss applied to the external auricular appendage! A kiss of such a suction force reminds one of Benedict's, which had "such a clamorous smack that, at the parting, all the church did echo."

The bad moral influence exercised upon girls and boys who, when approaching puberty, are fondled and overkissed is very truthfully and forcibly depicted by Dr. Adams. It cannot be denied that the promiscous kissing of children by strangers, or those comparatively so, is an extremely pernicious practice. This, we believe, is being realized by parents, and few nurses are sent out without directions not to allow the infant to be kissed. In the general gloomy view of kissing taken by Dr. Adams it is not necessary to share. Although we may not realize as he does the wide-spread and endemic character of the kissing habit in Washington, we can only trust it will prove a safe place for the International Congress. It would be a painful sight, indeed, to see the American Medical Association's honored guests going home disfigured with labial herpes and ulcerative stomatitis.

News of the Week.

THE PEDIATRIC SOCIETY OF NEW YORK.—At the annual meeting of this Society, June 4th, Dr. George F. Shrady was elected President.

A CASE OF HYDROPHOBIA CURED BY SWEATING is reported to have occurred at Odessa (*Lancet*, May 26th). The patient was a boy who had been bitten by a mad dog several days before the symptoms developed.

VIRCHOW'S JUBILEE.—Professor Virchow recently completed the thirtieth year of his occupancy of the chair of Pathological Anatomy at Berlin.

THE FUNCTION OF THE THYROID GLAND.—So much has been said about the importance of this gland that the following related by Dr. J. Pohlman in the *Western Medical Press* is of interest: "From three dogs, ordinary curs, picked up in the streets of Buffalo, I removed the entire thyroid glands on April 15th, 19th, and 22d, respectively, and all three not only survived the operation, but did well and have been improving in flesh right along up to date (May 23d), when they were used for other experiments."

Dr. J. P. Bramwell, Surgeon to the Perth Infirmary, also reports in the *British Medical Journal* of May 29th, the case of a young man whose enlarged thyroid he removed one year ago. The patient up to date has shown no signs of physical or mental deterioration.

AT THE ANNUAL MEETING OF THE FLORIDA STATE MEDICAL ASSOCIATION, May 18, 1886, the following officers were elected for the ensuing year: J. W. Porter, of Key West, President; A. W. Knight, of Jacksonville, Secretary; J. D. Fernandez, of Jacksonville, Treasurer. We note from the *Florida Medical and Surgical Journal* that the Society is prospering, and the profession in the State becoming better organized. Much credit for this is due to the *Journal*.

Phthisis and Pityriasis.—MM. Duguet and Héricourt, who made a communication to the Academy of Medicine concerning the identity of the microsporon of pityriasis vesicolor with the bacillus of tuberculosis (see *Journal*, May 14th), have written to say that further researches obliged them to withdraw the theories and opinions formulated in that communication.

Typhoid Fever in the United States.—About twenty-five thousand deaths from typhoid fever occur in this country annually, and this represents fully one hundred and fifty thousand cases of the disease. The hundred and twenty-five thousand persons who recover, lose six weeks out of their lives, and carry perhaps some vestiges of the fever's influence for years.

Dr. Henry Howard on Louis Riel.—Dr. Howard closes an account of his observations made upon Riel when confined in a lunatic asylum in 1876, as follows: "What I have written of poor Louis D. Riel I have not written for politicians nor for nationalists. I have simply written for the sake of imparting knowledge to the physical scientist or natural philosopher. I admitted Riel simply to protect him from his enemies, and for the same reason I recommended his discharge. I suspect his friends knew these facts, and that was why I was not brought to give evidence on his trial; because, if I were asked, 'Did he know right from wrong?' I would have been obliged to answer 'Yes.' From his own statement on his trial, he was pleased to think I did not consider him *insane*. But I did consider him an abnormal man, a man with a teratological defect in his psycho-physical organization; and if he was guilty of the crime of which he was accused, and I believed he was, he was guilty because he was like all other criminals—not an intellectual man, but a fool, one of the millions of the immoral, criminal fools that I have already written of."

The Strikes.—The present phenomena of the strikes are ingeniously shown by the *Boston Medical and Surgical Journal* to resemble the imitative diseases known as myriachet, "the jumpers," etc. The blind obedience and automatic unreasoning imitation shown in many of the strikes certainly suggests that they have in them the elements of a neurotic epidemic.

Compound Oxygen.—The *Journal of Chemistry* publishes again the well-known analysis of "compound oxygen." It is a solution of nitrate of ammonia, a solution which, taken internally or inhaled, can no more yield oxygen than so much cold water. This nostrum, comments the *Boston Medical and Surgical Journal*, which has so long imposed upon a credulous and easily duped public, owes its success largely to the conspicuous place it has held in the advertising columns of eminently respectable journals. That newspapers devoted to religion (or at least to some religious sect) should find it for their interest to make the management of their advertising columns a matter of business only, is not surprising; religious journals cause us surprise only when they rule out "medical" advertisements altogether from their columns.

An Effort to Secure the Endowment with the sum of $250,000 of the New York Homœopathic Medical College is commented upon by the *N. Y. Medical Times* as follows: "This institution does not represent medical science and art, but rather Hahnemann and Homœopathy. Is it not rather late in the nineteenth century, Messrs. Trustees of the New York Homœopathic Medical College, to appeal to liberal and intelligent men for aid to endow and dedicate to science an institution of learning devoted to the promulgation of one idea, and that idea embodying a fragment of the truths of therapeutics?"

Why Negroes have White Teeth.—Science occasionally illuminates the dark spots of our ignorance with such effulgence as to completely overpower one. As a case in point, we note the announcement in the *Florida Medical Journal*, that Southern dentists have discovered that the peculiar whiteness of the negro's teeth is due to the excess of white blood-corpuscles.

Opinions of the Action of the American Medical Association.—There is a very general consensus of opinion regarding the last meeting of the Association, and it is expressed well by the *New Orleans Medical and Surgical Journal*, which says: "We believe that the action of the Association in regard to the action of the Judicial Council on the admission of the delegates of the Philadelphia County Medical Society was unwise and, at this particular juncture, well calculated to alienate many of the most esteemed of our Eastern confrères. . . . We believe that the policy of the Association in regard to the organization of the International Congress has added but little to the prospect of a very successful meeting at Washington. In our opinion, conciliatory efforts should have been made to re-enlist the interest of our distinguished brethren who were at one time connected with the Congress."

The Nebraska State Medical Society held its annual meeting at Lincoln June 1st, 2d, and 3d.

The Michigan State Medical Society held its twenty-first annual session at Jackson, beginning June 9th.

Professor R. T. Edes has resigned the Chair of Clinical Medicine in the Medical School.

How to take the Temperature quickly.—This may be done, according to Dr. Fitaloff, by warming the thermometer till the mercury stands at 106° or over, then placing it quickly in the axilla, where it need remain only one or two minutes.

Photographing the Retina of the Living Human Eye.—Mr. W. T. Jackman, of Coggeshall, Eng., has (*Photographic News*) made some fairly successful photographs of the human retina.

Hunting for a Wet-nurse.—It is not *de rigeur* for the Queen of Spain to nurse her infant son, consequently her physician has had to hunt up a wet-nurse. So far he has had to interview and examine twenty-seven applicants for the honorable position of suckling a king.

Yellow-fever Inoculations.—Dr. H. M. Lane, of Carthage, Mo., while on a visit to Rio Janeiro was inoculated by Dr. Freire with the attenuated yellow-fever virus. Dr. Lane thinks it protected from the disease. We learn that some of the culture-fluid employed by Dr. Freire has been placed in the hands of the bacteriologists of Johns Hopkins University.

The "Middleton Goldsmith" Lecture of the New York Pathological Society.—A series of lectures on the "Pathology of the Peripheral Neuroses" is to be delivered next season.

Regulation of Veterinary Medicine in New York.—The passage by the last Legislature of the bill to regulate veterinary practice makes New York the first State to undertake this work. The law compels the registration of veterinarians at the county clerk's office, and makes it incumbent on those registering to have a diploma.

An Outside View of Us.—While we have pleasure in offering our congratulations on the measure of success attained by the American Medical Association during the last thirty-seven years, we cannot but regret the fact that such success is far short of what might have been expected from the grand army of surgeons and physicians in the United States. During the last few years those whom we are accustomed to look up to as the leaders of the profession on this continent are but poorly represented at its meetings, and the tendency appears to be to diminish their numbers year by year. When we consider the status of that greatest medical organization in the world, the British Medical Association, and see how immeasurably superior it is to the American Society in every respect, we are utterly unable to evince any great enthusiasm over the results of the St. Louis meeting. Why does the American medical profession allow this condition of things? Its Association seems to have fallen into wrong hands. Who is responsible for this?—*Canadian Practitioner*.

The Faculty of Medicine of the University of Vienna has had a steady increase in the number of its medical students since 1878, until in 1885–86 the number was 2,673.

Inoculation for Yellow Fever.—In a letter recently received from Dr. Domingo Freire, of Rio de Janeiro, by Dr. Joseph Holt, President of the Louisiana State Board of Health, the following statement is made, presenting a summary of the results claimed for his inoculation for yellow fever: "I have performed over seven thousand inoculations with full success. The immunity was almost absolute, notwithstanding the intensity of the epidemic this year. More than three thousand persons who were not inoculated died of yellow fever, while among the seven thousand inoculated, inhabiting the same infected localities, subject to the same morbid conditions, but seven or eight individuals whose disease was diagnosed as yellow fever died. My confrères here have the careless habit of not giving notice of the fact until after the interment of the individuals, and, consequently, accuse me of being unsuccessful. You therefore see that in spite of all this bad will my doctrine comes out victorious once more by the test of the year when the epidemic characterizes itself by energetic intensity of infection and contagion."

Discovery of the Active Principles of Cod-liver Oil—Morrhuol.—Dr. Lafarge, of Paris, has separated from cod-liver oil a substance containing all the active ingredients of the oil except the fat. This substance he calls morrhuol. It contains twelve times as much iodine, bromine, and phosphorus as the original oil, but these elements exist in a state of combination difficult to destroy. The quantity of morrhuol obtainable varies, according to the quality of the oil, from one and one-half to six per cent. When cod-liver oil is deprived of the morrhuol, it no longer possesses the properties which make it so valuable, and acts simply as a fatty substance. In order to cover the disagreeable taste of the morrhuol, it is best given in capsules containing five grains of the extract, corresponding to a drachm and a half of the crude oil. Two of these capsules a day in young children, or four daily in older children, have, Dr. Lafarge says, proved of great service in his hands. It also relieves the cough of phthisis.

Reviews and Notices.

Recherches sur le Microbe du Choléra Asiatique. Par le Dr. E. van Ermengem. Paris: G. Carré. 1885.

Die Cholera. Von Max von Pettenkofer. Berlin: S. Schottlaender. 1885.

Cholera; Its Origin, History, Causation, Symptoms, Lesions, Prevention, and Treatment. By Alfred Stillé, M.D., LL.D. Philadelphia: Lea Brothers & Co. 1885.

A Treatise on Epidemic Cholera and Allied Diseases. By A. B. Palmer, M.D., LL.D., Professor of Pathology, Practice of Medicine, and Clinical Medicine in the College of Medicine and Surgery in the University of Michigan. Ann Arbor, Mich.: Register Publishing House. 1885.

Cholera; Its Cause and Prevention. By Ezra A. Bartlett, M.D. Albany: H. H. Bender. 1885.

Cholera; Its Nature, Symptoms, History, Cause, and Prevention. One of the Somerville Course of Lectures. By J. B. McConnell, M.D. Montreal: Robert Miller, Son & Co. 1885.

From a nosological point of view the year 1885 may be aptly termed a "cholera year"—in foreign lands because they actually had this scourge, and in our own country because we were expected to have it. It is possible to conceive a tinge of disappointment arising in the breasts of those among us who, confident of their ability to successfully cope with the dreaded pestilence, found no opportunity to demonstrate their power. But, barring such exceptional beings, there was even in the ranks of the profession only satisfaction and congratulation that the dreaded visitor did not put in his expected appearance. According to a familiar adage, we were certainly forearmed, if easily accessible knowledge concerning cholera may be regarded as an equivalent of being forewarned.

The list of publications heading this notice embraces but a few of the legion of cholera books that have appeared in the year just passed. Nevertheless it is typical of much that has been recently written concerning a disease of which we know so little and which we still have reason to fear so much.

Dr. van Ermengem's now well-known researches are embodied in a work of three hundred and seventy-four pages, supplied with twelve plates containing twenty-four beautifully executed microphotographs. The volume contains chiefly the results of independent investigations carried on by its industrious author for many months. No more trustworthy or substantial corroboration of Koch's doctrine concerning the parasitic origin of cholera has yet been published. It may indeed be regarded as a complete monograph on the subject of the comma-

bacillus. The mechanical execution of this valuable and interesting work is such as to make us feel jealous of our transatlantic confrères. Certainly no American publisher would care to put a book on the market in such costly garments.

Pettenkofer's brochure of sixty-three pages contains a half-scientific, half-popular exposé of his peculiar views on the essential nature of cholera. He does not accept Koch's doctrine, and still struggles to maintain his older theories on the importance of subsoil water. He does this in face of the array of old and new facts, which show clearly enough that his position is not and never has been tenable.

Dr. Stillé's practical little treatise will prove very acceptable to the profession of our country. Within the compass of 162 pages the author has succeeded in giving a very fair representation of the present status of our actual knowledge concerning cholera. He declines to accept Koch's doctrine as proven, but is unable to give any more satisfactory explanation of the etiology of the disease than is contained in the German savant's theory. He very properly insists on the necessity of quarantine, "not in the literal but in the official sense of the word." The treatment he advocates is the simple one that experience has demonstrated to be alone admissible, all violent measures and special plans or methods being regarded by him as useless, if not barbarous. For a concise treatise on cholera, which does not pretend to supplant more complete works, we can heartily recommend this book from the facile pen of an unusually gifted author.

"A Treatise on Epidemic Cholera and Allied Diseases," by Dr. A. B. Palmer, is an incomplete and, in places, quite inaccurate compilation of the many different views held with regard to cholera, its nature, methods of propagation, prevention, and cure. There is little to make it acceptable to either student or practitioner, who will naturally much prefer Stillé's treatise.

The two little volumes last on the list have no distinctive features of their own. They may possibly be read with profit by the laity, but for physicians they are so fragmentary in the conveyance of their information that they must be classed with the ephemeral literature of the day.

The Surgical Diseases of Children. By Edmund Owen, M.B., F.R.C.S., Surgeon to the Hospital for Sick Children, Great Ormond Street, London; Surgeon to, and Lecturer on Anatomy at, St. Mary's Hospital; Member of the Board of Examiners at the Royal College of Surgeons. 12mo, 585 pages. With Four Chromo-lithographic Plates and Eighty-five Engravings. Philadelphia: Lea Brothers & Co. 1886.

This book is one of a series of clinical manuals intended for the use of practitioners and students of medicine. All of the surgical affections of childhood are taken up in turn and treated of briefly, but in a satisfactory manner. The work is by no means a complete treatise, and is not intended to be one, but is rather a concise handbook of the subject under consideration. The author wastes no time nor space in referring to theories or in the discussion of various modes of treatment. But we think, if the book were intended for American readers, that its value would have been considerably enhanced by a brief notice, at least, of methods employed by American surgeons, which we may be pardoned for believing are oftentimes superior to those of our transatlantic brethren. For this reason we cannot unhesitatingly recommend the manual as a trustworthy guide for the student or the young practitioner just starting out with but little practical, and a rather confused theoretical, knowledge. For everything except treatment, however, the book is an excellent one, and its perusal, we venture to say, will be beneficial to many a man whose remembrance of his student days has grown dim with time. And, if used in conjunction with other works, it will be of great utility to students as well. The book is very clearly printed, and the use of heavy type serves to emphasize the important points and to enable the reader to find what he wants without any loss of time. The illustrations are very well executed and judiciously inserted, so that they really illustrate the text, a purpose which wood-cuts and other engravings in medical works do not always serve.

Transactions of the American Gynecological Association. Volume X. For the year 1885. 8vo, pp. 354. New York: D. Appleton & Co. 1886.

Few volumes of "Transactions" are filled with more attractive and practical material than are those of the American Gynecological Association. The leading gynecologists of the country are its contributors, and the articles furnished by them are always worthy of permanent record. In other words, the papers which appear mark the progress of the science from year to year, as noted by those who stand on the mountain and have a wide outlook. This volume is fully up to its predecessors, which is speaking for it in high praise.

Lectures on Clinical Otology. By Henry C. Houghton. Pp. 260. Boston: Otis Clapp & Son. 1885.

The Diagnosis and Treatment of Diseases of the Ear. By Oren D. Pomeroy. Pp. 413. New York: D. Appleton & Co. 1886.

These two books represent widely different views on the subject of which they treat, especially in respect to therapeutics, the former presenting the subject from the homœopathists' point of view, the latter from the conventional standpoint.

Dr. Houghton's experiences are mostly in the use of drugs, as indicated by homœopathic provings in the treatment of ear disease, as based on symptomatology rather than on pathology. A large portion of the book, seventy pages, is given up to an appendix, ten pages of which are devoted to a list of abbreviations, and sixty pages to a repertory of drugs classified according to their physiological action. Anyone having an interest in this method of selecting remedies, may here find a most extensive and curious collection, evidently made with painstaking care, worthy of a plan promising more practical results than can be hoped to be derived from such rubbish. The more practical features of the book are derived from current otological literature, and altogether there is an amusing combination of heroic and infinitesimal methods as a result of the author's dual inspiration.

Dr. Pomeroy deals with the subject from the light derived from the obverse side of the shield, so to speak, his book echoing the views of the more gladiatorial pioneers in otology.

The scope of this book is not limited to any portion of the field of otology, and the author is most industrious in the citation of opinions. It would, perhaps, have been more fair had the source of many of the views brought forward been given, but on the other hand, accredited citations might have been omitted without giving offence. A perusal of this book is liable to leave quite a different impression than is given by the former—that the author is rather prone to regard the ear, when diseased, as an organ that should be coerced back to its normal state by energetic means—and those who would know the methods that have been thus tried, or perhaps it should be said adopted, for this purpose, will be gratified by the author's treatment of the subject.

Dr. Houghton's literary style is good, while Dr. Pomeroy is lacking in ease; the book of the former is a credit to the publisher, the make-up of the other is not so good, the illustrations being especially bad—for example, the picture of the "normal" drumhead, as shown on page 42, is probably the worst of its kind that ever found its way into a book.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 3, 1886.

ABRAHAM JACOBI, M.D., PRESIDENT, IN THE CHAIR.

THE CORRESPONDING SECRETARY acknowledged the receipt of a donation of bound volumes to the library from Dr. Pliny Earle, of Northampton, Mass., who was one of the founders of the Academy, and who read before it the first paper.

THE PRESIDENT announced that he had received a communication from Julius Althaus, of London, England, a Corresponding Fellow, from whom, as he hoped, the Academy would have the pleasure of hearing a paper in October next.

The President introduced Dr. Samuel C. Busey, of Washington, and invited him to take a seat upon the platform. Ex-President Fordyce Barker also was invited to take a seat upon the platform.

DR. C. C. LEE then read a paper [see p. 670], entitled

THE FUTURE INFLUENCE OF SURGERY AND SURGICAL RESOURCES UPON OBSTETRICS.

The discussion was opened by DR. W. M. POLK, who said that he would not attempt to speak on the operations which Dr. Lee had described so graphically, and which were a sufficient answer to the question implied in the title of his paper. When he began to teach it was in the department of general medicine, therapeutics, and materia medica. But in the course of time he began to teach obstetrics, and he went from one department into the other with the feeling that much the larger part of obstetrics was in the domain of medicine. His education, doubtless, had had much to do with that sort of feeling, for it had been largely influenced by the most accomplished teachings of Professor Fordyce Barker, and he was free to confess that when he stuck to the doctrines inculcated by that eminent teacher he had rarely gone wrong. However, he saw, after a while, that there were certain surgical bearings, which, if neglected, would soon push the practitioner to the wall, and stick him to the wall, and that fact led him to look into the history of the entire question, from which he had been brought to the conclusion that the most successful obstetricians had been those who united as thoroughly as possible the qualifications of the accomplished physician and the skilful surgeon. He had also been led to think that the tendency of the obstetric surgeon was perhaps to do a little more with his knife than his cases demanded. For example, immediate repair of laceration of *the cervix* during parturition, he believed, might better be left to nature aided by cleanliness, rather than at once to resort to operative interference.

But, surgically speaking, obstetricians had been obliged to fight their way against the opposition of those who were imbued with the idea of the mere physician, on the one hand, and upon the other hand, the active opposition of those who were engaged in general surgical work. But, as evidence that finally an enviable position had been attained, he had only to point to the results which had been secured in abdominal surgery. He had no doubt whatever that those who were engaged in abdominal surgery would soon settle the question of Cæsarean section successfully; that the day would come, and was not far away, when craniotomy could be eliminated from obstetric operations; and when that could be done, and successful Cæsarean section could be substituted for it, they would be in a position to say that the greatest work ever accomplished in surgery belonged to obstetricians.

DR. J. H. FRUITNIGHT regarded immediate repair of a lacerated perineum as one of the greatest advances which had been made in obstetric surgery, notwithstanding the fact that nature frequently does the repairing satisfactorily. If craniotomy could be relegated to the past, and Cæsarean section become the substitute, it would be one of the greatest triumphs which obstetrics could achieve.

DR. FORDYCE BARKER thanked Dr. Polk for his kind and complimentary remarks, and said that he was willing to accept the position of one belonging to the class known as midwives, in the sense that he was not a surgeon. Very soon after he began to practise in New York he found that he had in the surgical field such competitors as Marion Sims and others, and, having a natural dislike to procedures belonging to this class of cases, he believed that he exhibited some sagacity by referring the operations belonging to surgical obstetrics to his colleagues, and in giving his attention to those which belong purely to obstetric art. The progress in obstetric surgery had been so rapid that he had been unable to keep fully apace with its advance, and constitutionally he was not inclined to accept new propositions because they were new, and, on the other hand, was not inclined to deny their truth because they were new; yet he would express his opinion on one point in the paper, the whole of which he was unavoidably deprived of the pleasure of hearing, and that was with regard to *primary operations for lacerations of the perineum with parturition*. He recalled the statement of an eminent member of the profession, who once said that "any physician who did not close by the immediate operation a laceration of the perineum neglected to do his duty." At the time it struck him as rather a strong proposition to make, and also rather doubtful, but he did not antagonize the view, and thought that he would wait for its proof, and he had been waiting ever since. Perhaps he might be biased by one fact—the utterance of which might seem a little pugnacious, but he challenged contradiction—and it was that in no case in his own private practice had even the secondary operation been performed by any of our surgical gynecologists; in no case had it been required. He did not mean to say that he had never met with laceration of the perineum, for he had had these cases, but he had watched them closely, and in every case the secondary operation had not been performed by anyone. In his hospital practice such cases may have occurred, but not in his private practice. He was willing to go still further and say that in no case of his had the primary operation been performed until last winter; last winter he had one in which he thought that the primary operation was necessary, and it was performed. Although the greatest care was taken of the patient, union did not take place. The case was one of *justo minor* contraction of the pelvis, in which he delivered a living child, weighing eleven pounds, with Simpson's modification of Tarnier's forceps, and extensive laceration was produced.

Between the first of February and the first of May he had seen, in consultation, forty cases, which presented a peculiar train of symptoms. Previous to the sixth day after confinement there were no symptoms, and then they exploded violently, with extremely rapid pulse, temperature of 104° to 106° F., etc. These violent symptoms, in all the cases except one, disappeared within three days. Only one patient died. Of the forty, five had had the primary operation performed; in only one did union take place. He had repeatedly watched the result of the primary operation after it had been performed by others, and in two cases he had seen profuse hemorrhage in consequence of the shock and exhaustion. In other cases he had been informed that the operation was successful.

Dr. Barker then referred to special cases. One in which, with the first labor, extensive rupture of the perineum occurred, and union occurred spontaneously. In the second labor, a very extensive laceration took place up to the sphincter. In that case he called Dr. Lusk in consultation, who was an advocate of the primary operation, but thought it unadvisable to operate in that case,

and the patient, Dr. Barker thought, had very good union. Another similar case was narrated briefly.

Dr. Barker, therefore, would say that he had seen very many cases in which complete union had taken place, sufficient for all practical purposes, the laceration never having interfered with the position of the uterus or the comfort of the patient; and now, for the first time, he would say that he thought there were many cases in which the circumstances and conditions were such that it would be wise to perform the primary operation, with the hope that union would take place without exhausting the patient; but that in every case the question must be decided by a careful analysis of all the symptoms and conditions. As a general rule, however, he would say that it was safer to avoid the operation, trusting to absolute cleanliness, watchfully seeking for the healthy performance of all the general functions to effect a cure, and in the large majority of cases recovery will take place without the operation.

With reference to the title of the paper, there was no doubt that the future influence of surgery and surgical resources upon obstetrics would be very great; but it seemed to him that the real influence was that which gynecological and obstetric surgery had produced upon general surgery. Dr. Barker then referred to the remarkable paper on "Laparotomy for Penetrating Wounds of the Abdomen," read before the Academy by the late J. Marion Sims, and to the remarks made in reply by the late James R. Wood. Professor Wood's argument was that gynecological surgeons had opportunity to prepare their patients for this class of operations, whereas the general surgeon was called upon to operate under entirely different circumstances, with the patient suffering from, or just emerging from, severe shock, etc. In the majority of cases this was, perhaps, true, and in general the better the condition of the patient, the more likely was the operation to be successful. But the argument did not hold in all respects; there was another side to that view. It was a general principle, well established, that where a source of irritation which was rapidly destroying the patient could be removed by an operation, it was an argument in favor of performing it under circumstances as unfavorable as any which the general surgeon had to meet. This principle was announced by Sir Spencer Wells, and until then the existence of peritonitis or pus in the abdomen, due to the existing tumor requiring operation, was regarded as a contra-indication; but guided by it, such conditions were to be regarded as indications for the performance of the operation. The application of this principle was illustrated by a case in the practice of the late Washington L. Atlee, and Sir Spencer, who was present, said, that "although it is not a favorable case, it is the duty of the operator to perform the operation." Dr. Barker thought that not a single person present at the operation expected that the patient would recover, but she did make a good and prompt recovery as soon as the source of irritation was removed.

Dr. Malcolm McLean spoke in favor of the primary operation for lacerated perineum, always using a soft suture like silk. He had not seen it do any harm, and in these days, at least, it gave moral support in a case of non-union.

Dr. H. J. Boldt entered his protest against the primary operation for laceration of the cervix during parturition, unless there was some urgent indication, like profuse hemorrhage, evidently due to the injury.

Dr. Polk, in reply to a question asked by Dr. Barker, said that his views regarding the primary operation for lacerated perineum coincided with Dr. McLean's, although there were many cases where the shock of the operation would be such as to make it unjustifiable to subject the patient to it. His rule had been to introduce a suture in most cases, and he always used the silk suture; indeed, he had abandoned the use of wire in all operations, whether primary or secondary.

Dr. Lee, in closing the discussion, said that it was his custom to perform the primary operation for lacerated perineum, using silk suture and perhaps two or three catgut sutures. He had not seen shock increased by the operation. Although he had seen cases in which he thought it inadvisable to do any operation, he thought that, in the great majority, the primary operation, if done properly, quickly, gently, and while the patient was under an anæsthetic, would not produce shock, nor would it increase the chances of the occurrence of septicæmia. So far, his cases had done well, but he had seen a great number of disastrous results which came from neglect to perform this simple operation.

The President announced that the following

AMENDMENT TO THE CONSTITUTION

had been adopted:

"The Academy may suspend or expel a Fellow for violation of its regulations, or the commission of any act which unfavorably affects the character of the medical profession or the interests of the Academy."

The Academy then adjourned.

PENNSYLVANIA STATE MEDICAL SOCIETY.

Thirty-Seventh Annual Meeting, held in Williamsport, June 2, 3, and 4, 1886.

WEDNESDAY, JUNE 2D—FIRST DAY.

The Society was called to order by the President, Dr. E. A. Wood, of Pittsburg.

Dr. Helsby made the address of welcome, and as Chairman of the Committee on Credentials reported

A PROTEST AGAINST THE ADMISSION OF THE PHILADELPHIA DELEGATES.

The protest was signed by Drs. King and Taylor, who had made the minority report of the delegation to St. Louis. The protest had been referred to the Judicial Council, and following precedent rather than parliamentary usage, the delegates had been denied registration. Several motions referring to the matter were ruled out, and the president announced that the Judicial Council would report at 2 P.M.

Dr. Theophilus Parvin, President of the American Medical Association, was observed in the auditorium, and was invited to the stage.

Dr. Parrish offered a resolution

REAFFIRMING ADHERENCE TO THE CODE,

which was adopted.

Dr. H. H. Smith presented the

REPORT OF THE DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION,

and Dr. Mills presented a minority report, in which, referring to the exclusion of the Philadelphia delegation, he mentioned

THE NOTABLE ABSENCE OF DELEGATES FROM THE EAST AND NEW ENGLAND.

He said that meetings of the American Medical Association were never fairly representative; when held in one section

AFFAIRS WERE CONTROLLED BY A SECTIONAL VOTE.

At the St. Louis meeting the members generally did not understand the question, and every attempt to bring the matter before the meeting, so that they might do so, was shut out in a manner that was scarcely courteous. Both the majority and minority reports, of Drs. Smith and Mills, were accepted.

Dr. Edward Jackson, of Philadelphia, read a paper on the

RELATION OF EYE-STRAIN TO HEADACHE,

mentioning the frequency of such connection. Few persons have not felt it. The tendency of business and

amusement is to tax the eyes more heavily. He recited the history of cases showing how excessive accommodative effort is necessitated by the presence of hypermetropic astigmatism and other errors of refraction, and how the resulting headache is often relieved by correcting-glasses, duboisia, rest, etc. Eye-strain is not a sole cause, however, but one of several factors. It is an important one, because it can often be removed, and its removal gives relief. He mentioned other causes of eye-strain besides errors of refraction, as insufficiency of the recti, citing instances where the failure had even been with the upper and lower muscles.

The Chairman ruled that the

PHILADELPHIA DELEGATES OF LAST YEAR SHOULD HOLD OVER

until the status of those of this year should be settled, which on appeal from the decision of the chair was affirmed. Dr. Dulles offered a resolution that the sense of the Society was that

DELEGATES SHOULD NOT BE DENIED REGISTRATION NOR RIGHTS PENDING JUDICIAL INVESTIGATION BY THE COUNCIL.

It was laid on the table amid much excitement, but was called up in the afternoon session and passed almost unanimously, on its abstract merits—it being then too late to affect the present question.

Dr. Tyson, of Philadelphia, gave the report of the Committee on

COLLECTIVE INVESTIGATION.

The subject chosen had been Rheumatism. Ninety-one replies had been received. Little of importance had been elicited. The Committee was continued for another year.

CONTROLLING MEDICAL LICENSES.

Dr. Jackson, from the Committee on Education, reported a bill for presentation to the Legislature, to create a commission to control licence to practise medicine, the members to be nominated to the Governor by the medical profession, and to have no connection with colleges.

Dr. H. C. Wood eloquently supported this effort to obtain some control of medical education. Much discussion ensued, but a motion to indefinitely postpone was lost by an overwhelming majority, and the report was accepted, and referred to a committee of five to bring the bill before the Legislature.

Dr. J. M. Anders, of Philadelphia, opened the afternoon session with a paper on

HYGIENE AND STATE MEDICINE,

comprehending the subjects of Isolation, Disinfection, Pure Drinking-water, and the formation of a Health Bureau, all as means of preventing contagion and infection. He commended the bill for the creation of a Health Bureau, now before Congress.

Dr. Dulles, of Philadelphia, read a paper on

SOME RECENT ANNOUNCEMENTS OF PASTEUR ON HYDROPHOBIA.

Pasteur has claimed to have inoculated 950 cases, with 7 deaths, but hundreds of these cases announced as cures were bitten by dogs which were not mad.

Dr. Pancoast remarked that should some of these patients develop hydrophobia it would be

INTERESTING TO KNOW WHETHER IT ORIGINATED IN A BITE OR IN THE INOCULATION.

Dr. Mills doubted if we had many, or even *any*, authenticated cases of true hydrophobia in recent years. He had examined five cases, and made post-mortems in alleged cases, which proved to be other diseases, such as tetanus, epilepsy, etc. Dr. Mills considers the certificates which Pasteur requires, that the patient was bitten by a *mad* dog, worthless. He has found some thirty diseases which may be mistaken for hydrophobia.

AN ADDRESS ON LARYNGOSCOPY

was made by Dr. Charles E. Sajous, of Philadelphia. He said the laryngoscope is not often enough used by the general practitioner; without it he gropes in the dark. The necessary instruments are not numerous or expensive. By proper examination the practitioner can discriminate between laryngeal phthisis and syphilitic ulceration in a moment, and cure the latter promptly by the treatment which would be injurious in the former. In laryngeal phthisis feeding by the tube is often valuable, and cocaine is an important adjunct. Cocaine is not so valuable in hay fever as claimed. Dr. Sajous has only succeeded with it in forty per cent. of his cases. An overdose of cocaine can easily be given by spray; he had one patient who was threatened with asphyxia for six hours after using it. In some forms of catarrhal headache Dr. Sajous had found insufflation of morphia, grain one-eighth, on each side, and carried as high as possible in the nasal cavity, to give good results. In hypertrophic rhinitis, chromic acid fused on a probe had been effective.

Dr. Solomon Solis-Cohen read a paper on

COMPRESSED AIR IN THE TREATMENT OF PULMONARY CONSUMPTION.

which he characterized as an old treatment, recently exploited under the name of "Pneumatic Differentiation," which, he said, dilated occluded alveoli, furnished a larger volume of air, increased the ventilation of the lungs, and exercised beneficial pressure on congested vessels. All this on the simple mechanical principle of greater pressure within than without.

Thursday, June 3d—Second Day.

The Judicial Council reported the

PROTEST AGAINST PHILADELPHIA DELEGATE NOT SUSTAINED.

The announcement was

RECEIVED WITH A ROUND OF APPLAUSE.

Dr. Carpenter, of Schuylkill, read an address on

MENTAL DISORDERS.

He said only twenty per cent. of insane patients sent to asylums recovered; that more could be cured by proper care. Enumerating causes of insanity he laid stress on our fast American life, the sensationalism of the press leading to insanity and crime, early addiction to tobacco and alcohol, the strain of political excitement, speculation, etc. The Society resolved to urge county societies to appoint committees to visit asylums to investigate the condition of insane patients, and see that they received proper treatment and had good sanitary environment.

Dr. Murdock, of Pittsburg, read a paper on the

RELATIVE VALUE OF MANIPULATION IN THE REDUCTION OF HIP-JOINT LUXATION,

in which he indicated his preference for other methods. He mentioned a number of cases in which good surgeons had failed to reduce this dislocation by manipulation, and had succeeded by extension with the heel in the perineum.

Dr. Packard read a paper on

SOME FURTHER CONSIDERATIONS ON TRACHEOTOMY.

He thought that tracheotomy will never become a "medical operation." It is often a difficult undertaking, requiring surgical skill. He sometimes omits anæsthetics when the child is already in a state of asphyxia. Chloroform is sometimes preferable to ether, and free incision is advisable. He prefers the high operation, and to have the thyroid isthmus drawn down by a blunt hook; he does not fix the trachea by a tenaculum, but if one be

used that having a double hook is preferable, as it admits incision between the prongs. A dilator or dressing-forceps should be used if time permits, so that the character of the excretion may be noted, and this should be swabbed out both above and below by clean, new sponges, held in bent forceps, and the sponges should then be destroyed. It is well to piece out the tapes with an elastic loop.

The simplest tubes are the best, and he prefers the single tube if cared for by a skilled attendant. Especially after the first few days the tube should be considered but a temporary expedient, and on the fourth or fifth day he tries the experiment of removing it. Topical medication should be commenced as soon as the first sleep passes off. Steam spray is valuable, and pulverized borax, alum, Condy's fluid, permanganate of potash, Labarraque's solution, etc., may be used. His experience with nitrate of silver has not been favorable; lime-water vapor is often overdone. A moist atmosphere at 70° or 75° is preferable to the exhausting higher temperatures. Tonics and suitable foods are important. After a few days he uses a tube with the back cut away, which permits more air-space in the trachea. The doctor then described "Intubation," but could find nothing in the method to recommend it.

Dr. H. L. Orth, of Dauphin County, read a paper on

THE TREATMENT OF INTRA PERITONEAL HÆMATOCELE

by incision and drainage, with an illustrative case, which recovered, after incision from above, with drainage and antiseptic dressing.

Dr. A. G. Heyl, of Philadelphia, read a paper on

THE APPLICATION OF MOIST HEAT IN THE TREATMENT OF PURULENT OPHTHALMIA,

stating that this disease is a frequent cause of blindness, that it is important for the general practitioner to understand and treat it skilfully. It is caused by a micro-organism; he described the gonococcus of Neisser and the method of its propagation. The cylindrical epithelium of the palpebral conjunctiva is the culture-ground of the gonococcus; hence the utility of nitrate of silver applied to that part. He had found the application of very hot water, applied like a poultice on absorbent cotton, and renewed every quarter of a minute for five minutes, three times a day, very useful.

Dr. Randall thought a weak solution of bichloride of mercury was unsurpassed, and had been found unirritating.

Dr. Jackson confirmed these views.

Dr. A. S. Roberts, of Philadelphia, read a paper on

FLAT-FOOT, WITH DESCRIPTION OF THE MECHANISM OF A NEW PLANTAR SPRING FOR ITS RELIEF.

The elastic plantar spring was made of tempered steel, with a fan-shaped flange, elevated on the inner side of the foot, to maintain the perpendicular as well as the horizontal concavity of the arch of the foot. He sometimes combines the ordinary ankle support and other appliances with the spring.

A resolution was adopted to urge the treasurers of county societies to aid with the "sinews of war" the Washington Committee in preparing a worthy entertainment for the International Congress.

THE OFFICERS ELECTED FOR THE YEAR

are: Dr. R. Davis, of Wilkesbarre, President; Drs. Allport, Kirlin, McKibbon, and Lohman, Vice-Presidents; Dr. Benjamin Lee, Treasurer, and Dr. W. B. Atkinson was re-elected Permanent Secretary.

Dr. J. V. Shoemaker read the

ADDRESS IN MEDICINE,

covering a wide field, of which space permits mention only of the duty of the profession toward the amelioration of the sanitary environment of working females (factory employees and others), their food, etc., closing with a tribute to the genius and memory of Austin Flint.

MISCELLANEOUS PAPERS.

Dr. Traill Green contributed another paper on "Hydrophobia," and Dr. Enfield one on "The Mineral Waters of Bedford County."

Dr. W. F. Waugh, of Philadelphia, read a paper on

SOME RARE PSYCHIC SEQUENCES OF TYPHOID FEVER,

noting Pasteur's theory that the immunity conferred by an attack of zymotic disease is due to destruction of the principles which are capable of sustaining the life of that disease-germ. An objection to this is that persons are supposed to be as well after this destruction of their tissues as before it. Dr. Waugh calls this in question, especially in severe cases of typhoid fever. He believes that it is unusual for such attacks to leave the victims as well as previously. The main object of the paper was to call attention to the occurrence, sometimes, of radical change in the disposition or moral status of the individual, falling short of actual insanity. He detailed two cases; one where a lady developed a passion for purchasing, giving away the articles or throwing them down a well. There were no symptoms of insanity, but a remarkable degree of acumen. These cases, and others, were the result of long-continued attacks of typhoid, with persistent high temperature. The deductions made were to use antipyretics, and to prevent the patient returning to work too soon after such attacks.

The Society visited the Williamsport Hospital, and in the evening listened to a practical address of the retiring President, Dr. Wood, to whose ability and decision the harmony of what promised to be a stormy session was largely due.

The programme for the third day consisted of an "Address in Obstetrics," by Dr. R. Leonard, of Carbon; "Additional Causes of Subinvolution of Uterus," by Dr. T. V. Crandall, Philadelphia; "Puerperal Convulsions," by Dr. W. H. Parcels, of Mifflin; and "The Antagonistic Drugs to be Employed in Typhoid Fever," by Dr. A. Enfield, of Bedford; and at 10 A.M. an excursion to Watkins Glenn closed the session.

The next annual meeting will be held at Bedford, Pa., on the last Wednesday of June, 1887.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

Eighth Annual Meeting, held in the Hall of the College of Physicians, Philadelphia, May 27, 28, and 29, 1886.

THURSDAY, MAY 27TH—FIRST DAY—MORNING SESSION.

The meeting was called to order at ten o'clock by the President, Dr. Harrison Allen, of Philadelphia.

After the calling of the roll the President delivered the annual address.

Following the presidential address a letter from the Secretary of the Philadelphia College of Physicians, tendering to the Association the use of the hall and the hospitalities of the College, was read.

Dr. Harrison Allen, of Philadelphia, read the first paper, entitled

TWO INSTANCES OF ADENOID DISEASE OF THE ROOF OF THE PHARYNX WHICH EXHIBITED UNUSUAL FEATURES.

The following cases were related as presenting certain points of interest.

Case I.—A. B——, aged five, much emaciated, without appetite, suffering with frequent attacks of indigestion, was sent to me in the latter part of January, 1884. Examination showed the roof of the mouth to be elevated, but the slightest attempt to depress the tongue was fol-

lowed by gagging. The nostrils were filled with a mucoid discharge, and a small quantity of a similar character was seen in the fauces after gagging. During the day the respiration was not exceedingly difficult, but at night it was greatly impeded. Almost directly after the child fell to sleep respiration became labored. After three or four inhalations breathing would cease, when it would open its mouth and make strenuous efforts to inspire. The child would then awaken and a forced inspiration ensue. It would then quickly fall to sleep and the same phenomena would recur, and in this manner the entire night would be passed. To these were occasionally added fits of crying and emesis. During an attack of whooping-cough the symptoms became much exaggerated, and were associated with irregular action of the heart.

Hypertrophy of the adenoid tissue of the pharynx, with unusual reflex phenomena, was diagnosed. On January 29th, with the patient under ether, the operation for the removal of this tissue was performed. An attempt was made to break down the tissue with the finger, but the presence of the latter arrested respiration. Efforts were then made to rasp the growth away with an instrument passed through the nose, but in a short time the patient showed symptoms of depression, and the operation was suspended. The pharynx was next seared with the hot wire. During the succeeding five weeks applications of iodine and glycerine were made, but there was no evident improvement in the breathing at night. The patient was again etherized and the pharynx shown to be empty. Suspecting that the tonsils might be the cause of the difficulty a portion of each one was excised. Still no improvement followed. A third attempt to detect the cause of the difficulty was made, and it was determined positively that the nostrils were patulous. A careful examination showed that during sleep the tongue fell backward, and that this was the essential condition. We then directed that when these attacks came on, the boy should be held with the face downward. The moment this position was assumed the child passed into a profound slumber. It was then so arranged that during the entire night the patient should be watched, so that the tongue should not have an opportunity of falling back. The boy prefers to lie upon his side, but when the attack comes on he turns on his face without awakening. He is now a strong and healthy boy.

Case II.—A girl, aged six. The irritability of the pharynx was excessive. The patient had been twice operated on by other surgeons, and it was inferred that an attempt had been made to remove morbid tissue. The patient was etherized with great care, and the entire nasal pharynx found to be much smaller than normal, and its roof was highly arched in form. The posterior slope of the roof was the seat of an adenoid growth. This was removed.

The patient was improved and two weeks later she was again etherized, and it was ascertained that all the nodules had been removed, but that the membrane at the roof of the mouth was exceedingly thick and tended to obstruct the passage of air. This was subjected to cauterization in several places. No further efforts were made to reduce the size of the membrane by operation, and the patient was treated as a case of perverted nutrition of the osseous system. Iodine and glycerine were applied locally. Under this treatment gradual improvement in the nasal respiration took place, and at the present time the child appears to be perfectly recovered.

Dr. Franklin H. Hooper, of Boston, described the following case of a little girl, eight years of age, of a neurotic temperament and very precocious. Nasal respiration had been obstructed, and articulation had been defective since the age of three years; hearing was also impaired. A large quantity of adenoid tissue was demonstrated. The removal of this was followed by great improvement in breathing and articulation. The breathing did not improve at once, but the use of the Politzer bag resulted in marked improvement. This had been previously tried without effect. From this time she began to grow nervous. Eight days after the restoration of hearing she complained that she could not keep still. In a short time symptoms of chorea developed, and gradually increased in intensity. The speech became affected, and for over a month she was unable to speak. The chorea assumed an exceedingly severe form. She was unable to sleep. Various remedies were tried without benefit. Finally urethran was suggested. The use of this drug was followed by quiet sleep. Since this time the child has continued to improve, and the chorea has now entirely disappeared.

Dr. Harrison Allen, of Philadelphia, remarked that Dr. Hooper's case was an evidence of the way in which the adenoid growths might affect the entire system. His case was noteworthy in view of the fact that the phenomena appeared after the removal of the growth.

Dr. J. Solis-Cohen then presented to the Society a paper by Professor Rafael de la Sota y Llano, M.D., of Seville, Spain, which on invitation was read.

Lupus of the Throat.

In illustration of the difficulty of diagnosis the writer related the following: In 1884 I was consulted by a physician on account of an affection of the throat. The patient was much emaciated, reduced in strength, and with a clay-colored complexion. He was sixty years of age. The trouble with the throat had commenced one year previously. He was unable to take anything but milk and broths. The tongue was covered with psoriatic scales. The pharynx was lumpy and of a wine-red color. The right tonsil was the seat of an ulceration extending from the pyriform fossa below to the middle of the uvula, and involving half that structure. Its borders were red and swollen, its surface lumpy and irregular, and of a hard and elastic consistence. Some pain was produced by palpation, but no bleeding. There was no trouble while talking, or on coughing. Liquids were swallowed without difficulty. Breathing was accomplished with perfect freedom. The submaxillary glands were swollen. The patient had suffered from rheumatism, but no history of syphilis could be obtained. Taking into consideration the history of the case and the age of the patient, I considered it an ulcerated epithelioma. This was concurred in by the patient's physician. Nevertheless, mistrusting the testimony obtained, antisyphilitic medication with mercurials was tried. This occasioned such bad results that it was necessary to suspend it. He was then placed upon the use of iron and bitter tonics, and such diet as he could take. The specific treatment was subsequently resumed, but the local lesion assumed such a bad aspect that it became necessary to give up the treatment. From the fact that the ulceration was unattended by pain I began to have some doubts as to its epitheliomatous nature. I next prescribed sodium arsenite in ascending doses, with a gargle of resorcin, and the use of iodoform on the ulcerated surface after the latter was washed with a solution of borax. For a month the ulceration continued to extend, and when I had lost all hope it stopped its progress and became covered with healthy granulations. Cicatrization went on and was complete in three months. The scar is irregular, elevated and depressed, hard and soft, the posterior portion being adherent to the pharyngeal wall. The lingual psoriasis continued. Restoration to health has taken place. It is now eighteen months since the ulcer healed. With this result I concluded that the case was one of lupus.

My experience with this and other cases of lupus of the throat has led me to conclude that the disease may make its appearance at any period of life. I have seen it more frequently in adults than in children, and more frequently in men than in women. I have been unable to obtain any information in regard to inheritance. I have not found that hard drinkers or smokers were more liable to suffer, nor have I found that great exertion of the voice, or exposure to irritating substances, the ap-

plication of the cautery, or other agents, had any influence in its production.

I have never had an opportunity of observing the initial manifestations; but I have been able to detect the involvement of sound tissues later in the disease. Sometimes the mucous membrane assumes a purple color, and swells up and becomes granulated. Then one or two nodules may develop and may attain the size of a pea. Sometimes they become prominent without any alteration in the appearance of the mucous membrane. They may remain superficial, or they may attack the mucous tissue, and also the submucous tissue. Their form is rounded and their surface is smooth. These nodules are distinguished by their rosy red color from leprous tumors. Unlike carcinoma, the tumors are usually quite distinct. On pressure they present an elastic resistance. This is greater than the hardness of inflammation, but less than that of epithelioma. The parts on which the tumor develops become rigid, and the natural movement is diminished or lost, contrary to carcinoma, which usually produces sharp lancinating pain, and to leprosy, which is generally accompanied with anæsthesia; there is in lupus no alteration of the sensitiveness of the part. After a shorter or longer period the tubercle softens and becomes ulcerated. The ulceration assumes two forms. In some cases the tumor becomes excavated to a considerable depth, while in others it is more superficial. These ulcers do not bleed on pressure. The cure is difficult and attended with the formation of scars. In some cases these ulcers develop in a slow way, while in others they start with astonishing rapidity. They may develop within a few days, or they may remain quiescent for months or years, and then take on destructive action. The healing of the ulcer is followed by the formation of irregular scars, raised in some places, depressed in others; red in the former, white in the latter. Adhesions to different parts take place. Cicatrization takes place slowly, and is easily destroyed. Infiltration always remains.

All agree that the cure of lupus of the throat is more difficult than the same process in the skin. In the cases which I have seen the same treatment which I have employed in external lupus I have found of service in lupus of the throat. I do not despise internal treatment, but use such remedies as are indicated by the general condition of the patient. This has an important influence upon the result of topical treatment. If the lupus is not ulcerated I apply caustic substances. Until a few months ago I used tincture of iodine. I have, however, found good effects from the use of lactic acid. I have used it in cases of lupus of the cheek and gums, and also of the larynx. I have met with no inconvenience from its use, except the pain, which varies in different cases. If the lupus is ulcerated, I sometimes use the lactic acid; more frequently I employ a wash of borax and cover the ulcer with powder of iodoform. I always prescribe a gargle of a one per cent. solution of resorcin. Patients thus treated have always recovered after a greater or less time. In some cases the cure has probably been realized in the natural course of the disease, rather than as a result of the therapeutic measures.

Professor Joseph Leidy, of Philadelphia, on the invitation of the Council, made some remarks on

INTERESTING POINTS CONNECTED WITH THE LARYNX.

The first point to which I shall refer is the aperture of the larynx. This aperture, which communicates with the pharynx, is a large, oblique opening, bounded above by the summit of the epiglottis and laterally by the aryteno-epiglottidean folds. The lower portion is formed by the notch of the arytenoid cartilages. Laterally on each side two eminences are quite prominent in the fresh larynx, an upper pair and a lower pair. The lower pair is produced by the carniculæ of the larynx which terminate the summits of the arytenoid cartilages. The text-books state that immediately above these there is another pair of cartilages. These are the cartilages of Wrisberg. I have rarely found these cartilages decidedly developed in the white subject. Where a prominence exists in the white subject, it is caused by a group of glands. Often in these a little cartilage may be found. In the negro the cartilages of Wrisberg are conspicuously developed. This point has also been referred to by European observers.

The next point refers to the vocal cords, as they are usually designated. While physiologically it is correct to speak of the vocal cords, yet anatomically it is not correct to speak of vocal cords. These bands are usually spoken of as the inferior thyro-arytenoid ligaments. There is another ligament extending between the thyroid and cricoid cartilage in front, and extending back to the base of the arytenoid cartilages. This is described as the middle crico-thyroid ligament. It is connected with the upper border of the vocal membranes. This connnection is very important. If the cricoid cartilage is broken or crushed, it must influence the action of the so-called vocal cords.

The vocal cords are influenced altogether by the muscles attached to the arytenoid cartilages. These are supplied by the inferior laryngeal nerve. Another muscle which may influence the movements of the vocal membranes is the crico-thyroid. This is supplied by a separate nerve, the superior laryngeal. Why this muscle should be supplied by a different nerve has not been satisfactorily explained. The muscles which operate the arytenoid cartilage are the posterior crico-arytenoid, the lateral crico-arytenoid, and the arytenoid muscle. These muscles are sufficient to produce all the movements of the vocal membranes. Other muscles, that is to say, the aryteno-epiglottidean and the thyro-epiglottidean muscles, have been described, but in my experience the development of these muscles is exceedingly uncertain.

A vote of thanks was tendered Professor Leidy for his communication.

Dr. J. Solis-Cohen, of Philadelphia, said that in regard to the cuneiform cartilages he had noticed that these were best developed in those who had the best control over their voice. The connection of the crico-thyroid membrane with the vocal cords was very interesting. There were two supposed paralyses of the larynx which presented exactly the same picture. One is the paralysis of the thyro-arytenoid muscle, giving the Indian-bow paralysis of the Germans. The other is paralysis of the crico-thyroid muscle, giving exactly the same appearance. The way to distinguish these paralyses is by placing the finger on the crico-thyroid membrane. If the membrane vibrates when the patient speaks, the crico-thyroid muscle is not paralyzed. In phonation the thyroid cartilage is fixed, and when the attempt to sound high notes is made the cricoid cartilage is drawn up by this muscle. The posterior crico-thyroid muscle, from its attachment, not only separates the vocal bands, but when they are made tense by other muscles its action is to increase their tension.

Dr. Joseph Leidy said he had never been able to see that the crico-thyroid muscle was related to the other muscles in the production of sound. He was glad to hear the explanation which had been given, which appeared to be a satisfactory one.

Dr. J. N. Mackenzie, of Baltimore, exhibited an instrument for fracturing the nasal septum.

Dr. Carl Seiler, of Philadelphia, exhibited an apparatus to be used in making sections of frozen heads.

Dr. C. E. Sajous, of Philadelphia, presented a galvano-cautery handle in which the wires were attached in the middle of the instrument, and both the wires and the electrodes were secured without the use of screws. The connections within the handle were made of copper, and heavier than usual, in order to diminish the resistance.

Dr. J. H. Hartman, of Baltimore, exhibited a form of

écraseur with extremities of different shapes, which could be used for various purposes.

The President announced the following as the Nominating Committee: Dr. T. R. French, of Brooklyn, Dr. F. I. Knight, of Boston, and Dr. G. W. Major, of Montreal.

Adjourned.

Afternoon Session.

The first paper, by Dr. F. H. Hooper, of Boston, was entitled

Concerning the Positions of Paralyzed Vocal Bands.

The paper was in part based on experimental work done in the Physiological Laboratory of the Harvard Medical School, and in part theoretical. Specimens and drawings illustrating certain points were shown. The reader stated that it was his purpose to inquire into certain influences which might combine to determine the positions of paralyzed vocal bands, and to ask whether we are always justified in assuming that a given position of immobile vocal band was indicative of the arrested function of this or that muscle of the intrinsic laryngeal groups. The speaker thought that a vocal band might assume different positions in cases of complete paralysis of the recurrent nerve, and he passed in review certain anatomical factors and physical causes which he thought might contribute toward producing the position which might happen to be present when seen reflected in the laryngeal mirror.

Dr. Hooper concluded by saying that in his judgment the larynx is such a complicated organ anatomically, it is subject to such changes at different stages of life, its shape is so different in different individuals, its nerve-supply is so great, the arrangement of its muscles so liable to anomalies, that, as surely as one attempts to formulate theories on the positions alone of paralyzed vocal bands—positions which may be controlled by intrinsic muscles of the larynx that are not paralyzed, as well as by those that are—just so surely will one be led unconsciously into erroneous mental inferences.

The next paper was by Dr. J. Solis-Cohen, of Philadelphia, and related

The Further History of a Case of Paralysis of the Posterior Crico-Arytenoid Muscles,

presented at the first meeting of the Association in 1879, with a report of the autopsy and the exhibition of a specimen. The history of the case was briefly given as follows:

A man, aged forty-eight, was brought to me with a history that for two years he had suffered from occasional spasm of the larynx, so that, on at least two occasions, he had fallen unconscious in the street. When a boy he had suppurative inflammation of the left ear, and ever since then the introduction of the finger into the ear would produce spasm of the glottis. On examination with the mirror, I found what we then considered to be the picture of paralysis of the left posterior crico-arytenoid muscle. The examination produced spasm on the other side. The patient was directed to carry with him nitrite of amyl, to be used when the attacks came on. This he did for a while with good results. He subsequently returned with the statement that the day before he had had a severe spasm from tickling in the ear. While illustrating this he had a violent attack in the office, requiring the use of chloroform to relieve it. The next day tracheotomy was performed. No other lesion could be found at that time. The spasms were still produced by irritation of the ear. Five or six weeks later he began to have paralysis of the right vocal band. The picture then became extreme, and after this time I never saw the larynx in any other position. The man gradually became blind, and developed other symptoms of locomotor ataxia. During the four years preceding his death I did not see him, but during this time he continued to wear the tube. He was able to speak well without occluding the tube.

At the autopsy all the parts that could be available in the examination were removed and submitted to Dr. William Osler for examination. No abnormal appearance was discovered in the brain. The optic nerve was small, grayish-white, and atrophied. Many microscopical sections were made of various parts. The left recurrent nerve seemed natural, although it will be remembered that the left cord was the first affected. The right recurrent showed a distinct line of demarcation between the healthy and the unhealthy fibres. Instead of the right muscle being atrophied, it was the left muscl which had undergone wasting.

Dr. Frank Donaldson, Jr., of Baltimore, read a paper on

The Functions of the Recurrent Laryngeal Nerve, from an Experimental Study in Johns Hopkins University.

The speaker first referred to the fact that all the muscles, with the exception of the crico-thyroid, are supplied by the recurrent laryngeal nerve. The nerve, therefore, contains fibres controlling both phonation and respiration, acting both upon the abductor and upon the adductor muscles. He then referred to the experiments performed by Dr. Hooper, of Boston, the results of which had been presented at the last meeting of the Association. Dr. Hooper had found that the constrictors cease to act when consciousness was suspended by the action of ether, and that abduction with dilatation of glottis was obtained by stimulating the recurrent laryngeal nerve when consciousness was suspended. Dr. Donaldson's experiments were made to test the correctness of these results. In five experiments under states of deep narcosis, slight narcosis, and almost complete consciousness, he invariably got adduction of the vocal bands under the application of stimuli with the induction coil at ten. In one case in which consciousness had been suspended under slight stimulation abduction was produced, while under strong stimulation adduction was obtained. It was then found that abduction was always produced when weak currents were employed, but adduction was obtained when stronger stimuli were used. He therefore concluded that the constrictors did not cease to act during profound narcosis or in suspension of consciousness from any cause, and that abduction is not always obtained when consciousness is suspended; it is with weak currents that abduction is produced, but as the stimulation is increased adduction takes place.

Dr. F. I. Knight, of Boston, said that even if a certain unanimity of opinion is reached, we shall have to adapt these results to the case of man by clinical and pathological observation.

In regard to abductor paralysis he thought that the whole question should be decided upon the position of the vocal process, without any reference to the cord. If the vocal process is found in the median line, it is fair to assume that for some reason the function of the abductor muscle has been abolished. A good deal of difficulty has been experienced by observers in determining when the vocal process is in the median line. To him the crucial test is by phonation. If you get a vertical glottis on phonation, without any movement on suspected cord, you have a sure case.

Dr. S. Solis-Cohen, of Philadelphia, said that it was important to distinguish between the automatic (respiration), the reflex (cough), and the psychic (phonation) functions of the larynx. A well-known physiological law is that the resistance which a nerve offers to the transmission of nervous force is inversely as the use made of the muscle which it innervates. No muscle is used more than the abductors of the larynx. The resistance of their nerves would, *a priori*, then, be supposed to be the least, and Dr. Donaldson's experiments show that they respond to a weak stimulus.

Dr. F. I. Knight, of Boston, read a paper entitled

LARYNGEAL VERTIGO.

The writer had been able to find fourteen published cases of laryngeal vertigo. To these he added two coming under his own observation.

The following points were obtained from a study of the reported cases: All the cases with the exception of one have been in males. The average at which the attack has occurred has been forty-seven and a half years. The cough which induced the attack was slight in six cases, spasmodic in two, and severe in three. Momentary loss of consciousness occurred in fourteen cases. One case fell, but declared that he had not lost consciousness. Dizziness is mentioned in eleven cases. In four cases there seems to have been decided evidence of laryngeal spasm; in one this was doubtful. In four cases there was marked congestion of the head and face. In two the patients were pale. Convulsive movements of the limbs occurred in three cases; in one the movements affected the face and head, and in another the face. In these cases there was no biting of the tongue, no frothing of the mouth, and no involuntary micturition. The speaker objected to the term laryngeal vertigo. There probably is no real vertigo in these cases in the sense of the vertigo seen in aural vertigo. There is simply giddiness or lightness of the head. These cases cannot be considered to be instances of *petit mal*.

The cause of the attacks is disturbance of the cerebral circulation, perhaps due to the compression of the large blood vessels of the chest and perhaps the heart. Even without this, the effect of rapid breathing is well known. This causes marked cerebral disturbance.

A paper by Dr. Frank Donaldson, of Baltimore, on

A CASE OF CONGENITAL DEFECT OF THE EPIGLOTTIS, ILLUSTRATING A FUNCTION IN DIGESTION,

was read by title.

Dr. D. Bryson Delavan, of New York, read a paper on

BUCCAL TUBERCULOSIS.

He had seen six cases of this affection. In the reports of twenty-four cases of tuberculosis of the tongue, in all but one the subjects were males. In twelve cases the lesion was anterior, in seven upon the side, and in one at the base of the tongue. In four the situation was not stated. The disease was primary in nine cases, secondary in seven cases. In the remaining cases it was not stated whether the disease was primary or secondary. The longest duration of a case of primary tuberculosis was two and a half years, the shortest ten weeks. The age of the oldest person affected was seventy years, and of the youngest not under twelve.

Six cases coming under the speaker's observation were given in detail. A point of interest in the first case was that this is the first case on record in which removal of the tongue has been followed by an apparent cure of tubercle. Sufficient time has not elapsed to speak positively as to the ultimate result. The operation was done in the latter part of December, 1885.

Dr. E. L. Shurley, of Detroit, thought that in these cases of so-called primary tuberculosis mistakes of diagnosis are sometimes made. He was not sure that the bacillus can be regarded as an absolute evidence that the disease is tubercle; in one case considered to be a case of tubercle of the larynx, and in which the tubercle bacillus was found, the patient recovered and is still living, five or six years later.

Dr. J. O. Roe, of Rochester, reported two cases of primary tubercle of the pharynx. The first case was that of a lady thirty-five years of age. Six months before coming under observation she suffered great pain in the throat. A well-marked lesion was found above the border of the epiglottis and at the base of the tongue. This improved under local treatment. Subsequently the ulceration returned, the patient ran down in health and died. The larynx was entirely free from ulceration. The second case was a gentleman forty-five years of age, who had tuberculous ulceration of the pillars of the fauces. Later ulceration of the larynx developed. Under the persistent application of iodide of amyl, continued for some time, the patient recovered and is still well, weighing two hundred and twenty-five pounds.

Adjourned.

Friday, May 28th—Second Day—Morning Session.

At ten o'clock the Executive Session was held, and the following business was transacted.

The following officers were elected:

President—Dr. E. Fletcher Ingals, Chicago.

First Vice-President—Dr. E. Carroll Morgan, Washington.

Second Vice-President—Dr. J. N. Mackenzie, Baltimore.

Secretary and Treasurer—Dr. D. Bryson Delavan, New York.

Additional Member of the Council—Dr. F. H. Hooper, Boston.

The following active members were elected: Benjamin F. Westbrook, of Brooklyn; Frank Donaldson, Jr., of Baltimore; Alexander W. MacCoy, of Philadelphia, and J. C. Mulhall, of St. Louis.

Professor Ramon de la Sota y Lastra, of Seville, Spain, was elected a corresponding fellow.

A proposition was presented with reference to the formation of a congress of American physicians and surgeons. The proposition was approved and the following committee, taken from the ex-presidents of the Society, was appointed to confer with committees from other societies: Dr. J. Solis-Cohen, Philadelphia; Dr. G. M. Lefferts, New York; Dr. F. I. Knight, Boston; Dr. F. M. Bosworth, New York, and Dr. E. L. Shurley, of Detroit.

It was decided to hold the next meeting in New York, the time to be determined by the Council.

The first paper was by Dr. E. L. Shurley of Detroit, giving observations

ON THE USE OF SOME OF THE NEWER REMEDIES IN DISEASES OF THE UPPER AIR-PASSAGES.

The speaker took up in detail some of the numerous new remedies, and gave the result of his experience in their use.

Dr. William H. Daly, of Pittsburg, read a paper on

THE SIMPLEST AND MOST EFFICIENT TREATMENT OF DIPHTHERIA.

The speaker stated that his object was to describe the calomel treatment.

The credit of practising and recommending this treatment in modern times belongs to Dr. William C. Ritter, of Pittsburg. Of the different forms of mercury, calomel is the best. The drug is to be given in doses of from two to five grains every one, two, or three hours. It may be given dry and washed down with a little ice-water, or it may be given in water. This is to be continued until the stools become frequent and contain in them gelatinous masses of a bright-green color, resembling chopped spinach. Then the interval is to be lengthened and the drug continued so as to keep up this condition of catharsis, the patient having two or three stools each day. It is better to lengthen the interval than to diminish the dose. In this way there is less liability to induce ptyalism. Very little depression follows these large and frequently repeated doses. Ptyalism does not often occur. Under this treatment the membrane exfoliates and reforms, if at all, with less readiness; the fever diminishes. The diet is to be of a light, nutritious character. The speaker had found it the most efficient of any treatment which he had employed, and was the simplest to use. The cardinal rule in the treatment is to give the calomel

until the condition of catharsis described has been produced. Under this method a greater number of cases will be saved than under any other proposed method.

Dr. E. L. Shurley, of Detroit, admitted that the internal administration of calomel is one of the most efficient remedies for croupous inflammation, but in regard to its efficiency in the treatment of diphtheria he did not agree.

Dr. Donaldson, of Baltimore, had seen the calomel treatment frequently tried, but without success.

Dr. Beverley Robinson, of New York, said that there was scarcely a remedy which had not at some time been recommended as a specific for diphtheria. Calomel has been thoroughly used, and finally given up because it did not accomplish what was proposed. He was convinced that epidemics of diphtheria, as of other infectious diseases, differ very much in virulency, and a remedy which is successful in one epidemic will entirely fail in another.

Dr. F. H. Bosworth, of New York, said that mercury possesses a specific value in the treatment of diphtheria. Diphtheria is a blood-poison which often kills by its toxic effect, but in a greater majority of cases it kills by leading to the development of croup. The affection of the larynx is not diphtheria, but a sequent disease. While mercury has no effect upon diphtheria, it has a specific effect in arresting the disease in the larynx called croup.

Dr. William H. Daly said that he did not recommend calomel as a specific. He simply stated that he had had a greater proportion of successes under this plan of treatment than under any other which he had tried.

Dr. E. Carroll Morgan, of Washington, read a paper on

THE QUESTION OF HEMORRHAGE AFTER UVULOTOMY,

with the description of an instrument for its arrest, and described the following case: A man, aged twenty-eight, whose uvula had been excised five days previously by another operator, came to him with the statement that the bleeding came on four hours after the operation, and had continued at intervals since then, a large quantity of blood having been lost. Various means had been tried to stop the bleeding without success. The parts were governed with a coagulum of the persulphate of iron. This was removed and the parts cleansed. The bleeding points were then seen. The uvula had evidently been greatly hypertrophied. The scissors had been used in the operation. There was no evidence of the hemorrhagic diathesis in this patient or in any member of the family. The parts being cleaned, the stump was seized with dressing-forceps and the hemorrhage was controlled. The galvano-cautery was applied and the bleeding stopped. In nine hours it recurred. The cautery was again used, and the stump dusted with the persulphate of iron. The following morning a copious hemorrhage took place, not less than a drachm a minute, by actual measurement, being lost. A careful examination was then made to detect any other source of hemorrhage, but none could be found. Chromic acid was then used and the hemorrhage stopped. At three o'clock the same day copious bleeding recommenced. Galvano-cautery again employed. There was not room for the application of a ligature. Torsion was tried without success. A small clamp used in retaining shirt-sleeves in position was then taken, the spring weakened, the teeth filed down, and was then applied. A string was attached to this and brought out of the mouth. This checked the bleeding and was allowed to remain for several hours. It was then removed and the bleeding did not recur. A search of the literature of the subject failed to show any instance in which such a procedure had been before adopted. In this case he thought that this device had saved the patient's life.

A careful study of the subject had enabled him to find seventeen other cases in which the hemorrhage after this operation had been profuse. Death has never resulted directly from the hemorrhage after uvulotomy. Where the bleeding is persistent, it is always arterial in character.

The speaker, in conclusion, said that a fatal hemorrhage had never followed uvulotomy. A persistent, alarming hemorrhage is only encountered in the rarest instances. A moderate bleeding, stopping spontaneously or by the use of the mildest applications, occasionally happens. A loss of a few drops of blood at the time of operating, followed by a slight oozing, is a common occurrence.

The most reliable surgical measures for controlling uvular hemorrhage are ligature, compression by a clamp or forceps, and the use of the actual cautery. The most reliable styptics are, in the order named, solid nitrate of silver, persulphate of iron, gallic acid, tannic acid, alum, the local use of ice, and vinegar. The most reliable systemic remedies are opium, acetate of lead, sulphuric acid, and ergot. To the paper was appended an exhaustive bibliography. The speaker recommended that in operating the object should be to restore the uvula as nearly as possible to its normal size, and that the entire uvula should not be removed.

Afternoon Session.

Dr. Thomas R. French, of Brooklyn, read a paper on

THE LARYNGEAL IMAGE AS SEEN IN PHOTOGRAPHS TAKEN DURING THE PRODUCTION OF TONES IN THE SINGING VOICE.

The speaker had made numerous investigations on this subject, and his observations failed to confirm the statements of most authorities in regard to the position of the vocal cords during the production of different notes. Different individuals evidently use different mechanisms in the production of different tones. The general result of his investigations seemed to indicate that in the production of low notes the vocal cords are separated to a greater extent posteriorly than anteriorly. In the production of the middle tones the vocal cords are parallel, and in the production of high notes the opening is widest in front.

The paper was illustrated by numerous photographs thrown upon the screen. The following papers were then read by title: "Clinical Notes on Prolapse of the Laryngeal Ventricles," by George W. Major, of Montreal; "Three Cases of Thyrotomy, Recovery in each Case with Good Voice," by Dr. Clinton Wagner, of New York; "Alarming Hemorrhage after Tonsillar Excision, arrested by Torsion of the Artery," by the same author.

Dr. William C. Jarvis, of New York, described

A NOVEL PROCEDURE FOR THE REMOVAL OF SUBGLOTTIC LARYNGEAL GROWTHS.

J. C——, aged thirty-five, consulted me on March 22, 1883, for the relief of a difficulty of speech and of breathing. The trouble with the voice was noticed two years before; the difficulty in speech appeared one year before coming under observation. The laryngoscope showed a mass of papillomatous tissue occupying the cavity of the larynx. The vocal cords and ventricular bands were not involved. The attempt was made to seize them during phonation with the Mackenzie forceps. Only a few pieces were removed. The écraseur was then tried, but it was found impossible to use this instrument on account of the wire being seized by the spasmodic contraction of the vocal bands and displaced. Chromic-acid applications were now tried, but although the growth was touched, it was found impossible to limit the application to the diseased structures. The patient disappeared, and did not return for a year. His condition was much worse, and the difficulty of breathing greatly increased.

I then determined to try the following plan, and if this

failed, to remove the growth through an opening in the windpipe. Forceps similar to the Mackenzie instrument, but heavier, was secured. Through the tips of the blades holes were drilled, and through these was passed a piece of No. oo piano wire, which was conducted through a second opening at the angle of the blades and out to the handles, where it terminated in a loop, into which the extremity of the index-finger could be placed. When the blades were separated this wire formed a cross-bar uniting their extremities. When the blades were closed the loop of wire could be drawn up by the finger. The operation was performed without an anæsthetic. The tongue was depressed, and with the aid of the mirror the forceps were introduced into the cavity of the larynx. The mirror was then removed, and the forceps carried down to the glottis, through which the tip of the instrument was forced with considerable trouble on account of the spasm. The instrument was carried into the trachea sufficiently far to be sure that it was below the attachment of the growth. The blades were then separated, and pressing against the anterior wall of the larynx, the instrument was gradually raised until the wire was caught. The blades were then closed and clamped, the loop of wire drawn in, and the forceps removed, bringing with it a growth. The laryngoscope showed a second growth, which was removed in the same way. Breathing was at once rendered easy, and the speech became natural. The patient said that the presence of the forceps caused no pain. This is the only case on record of the removal of a subglottic tumor without anæsthetization, and without an opening into the larynx.

Dr. T. Amory de Blois, of Boston, read a paper on

CASES OF LARYNGEAL ŒDEMA.

The author gave brief details of fourteen cases of laryngeal œdema coming under his observation. All of these cases recovered; six under the use of astringents and eight after scarification.

Dr. Frank Donaldson, of Baltimore, suggested that in these cases intubation of the larynx after the O'Dwyer method might be applicable.

A paper by Dr. Charles H. Knight, of New York, describing a case of perichondritis of the larynx, was read by title.

Dr. Edgar Holden, M.D., of Newark, described

A CASE OF GUMMATOUS DISEASE OF THE LARYNX, WITH SPONTANEOUS REOPENING OF THE LARYNX AFTER THYROID LARYNGOTOMY.

L. D——, aged thirty-five, presented himself May 20, 1885, with dyspnœa and aphonia. Examination showed a cicatrix on the epiglottis, and the left side of the larynx presented a rounded mass of dull appearance. He denied syphilitic infection. After a careful consideration of the case the probabilities were thought to favor syphilis, and he was given iodide of potassium in large doses. There was improvement for a short time, but he soon became intolerant to the drug. Thyroid laryngotomy was considered necessary and was performed. The tumor was removed with the écraseur; no ulceration was visible. Tracheotomy was then performed, and the upper incision closed with sutures. The patient did well, and the tube was removed on the tenth day. The external wound healed. He insisted on returning to his home, where the surroundings were very unfavorable, and his health deteriorated. On the fortieth day after the healing of the wound the laryngeal incision was torn open by a severe cough. He refused to return to the hospital. Examination of the larynx showed no disease. Under the surroundings it was impossible to get the wound to heal. His health continued to run down, and six months and fourteen days after the operation the patient died of exhaustion. The patient had lived five months with an opening in the larynx.

Dr. U. G. Hitchcock, of New York, read a paper on

GUMMATOUS INFILTRATION OF THE BASE OF THE TONGUE,

giving the details of four cases coming under his observation. In none of these cases was the fibrous septum the exclusive seat of the disease, and in three cases the deposit did not approach this structure. In these cases the degree of dysphagia was in direct proportion to the proximity of the deposit to the base of the tongue.

Adjourned.

Saturday, May 29th—Third Day—Morning Session

A paper on a case of hysterical sneezing, apparently cured by applications to the nasal passages of the continuous battery current, by Dr. S. Solis-Cohen, of Philadelphia, was read by title.

Dr. John N. Mackenzie, of Baltimore, read a paper entitled

A CONTRIBUTION TO THE PATHOLOGY AND TREATMENT OF THE RESPIRATORY VASO-MOTOR NEUROSES.

These probably depend upon some form of sympathetic or vaso-motor irritation. In the production of such conditions two elements enter—a depraved state of the nerve-centres, and an abnormal excitability of certain portions of the naso-bronchial tract.

After a *résumé* of the pathological questions involved the subject of treatment was taken up.

In the treatment of hay fever the chief indications are to remove any existing local respiratory disease, to so alter the nutrition of the nerve-centres that they may not respond so easily to irritation, and to carefully search for pathological conditions and adopt appropriate treatment for their removal when found.

These chronic neuroses require long treatment. The peculiarity of the sympathetic is with the patient all the time, by night and by day, and at any moment may give evidence of its presence by a paroxysm. Any treatment which is practised simply during the attack or immediately before is simply palliative. In reference to the use of cocaine, he had found that it increased the irritability of these structures, and its application to the erectile tissue may ultimately weaken the cell-walls. He, however, did not question the excellent virtues of this remedy in certain acute affections. In hay fever he had failed to find improvement after its use. For a short time amelioration was produced, but in the course of an hour the symptoms recurred. His custom is to treat hay fever as any other chronic disease of the nervous system. He insisted upon a prolonged tonic course of treatment during the intervals. This may at first fail, but if persisted in, the time will come when, if there is no incurable lesion, the paroxysms will diminish in severity and frequency. The great mistake is made in the suspension of the treatment upon the termination of the attack. Among the remedies for the constitutional management of this class of cases he recommended phosphide of zinc, quinine, and nux vomica. These may be given in combination in the following proportions:

℞. Zinci phosphide ..... gr. $\frac{1}{16}$.
Quiniæ sulphat ..... gr. ij.
Ext. nucis vomicæ ..... gr. $\frac{1}{4}$.
Sig.—To be taken before meals.

After meals he directs that from three to five drops of liquor arsenici et hydrargyri iodidi be taken in a wineglassful of water. A similar line of treatment had been employed for several years by the speaker, in simple inflammatory conditions of the nose and throat, with good results. He had also employed bromide of potassium with advantage. A constant current of from ten to fifteen cells, with one pole over the nape of the neck and the other over the region of the superior cervical ganglia or in the nasal passage, had in a few cases been beneficial. In one case improvement followed the obliteration of vessels on the posterior wall of the pharynx.

In regard to topical applications to the existing nasal conditions, these accomplish one result only. They close one door to irritation of the nerve-centres. In many cases this is of itself sufficient. There are other cases in which such a course will fail. In these neuroses we cannot expect to thoroughly eradicate the disease until the sympathetic nerve irritation is overcome.

Dr. William H. Daly, of Pittsburg, said that the iodide of sodium has given him better results than any other single remedy. In all cases of this kind the upper air-passages should be carefully examined, and upon the slightest suspicion of local disease the condition should be remedied.

Dr. E. Carroll Morgan, of Washington, remarked that in considering these cases of hay fever he had been struck with the apparent immunity from this affection experienced by those suffering with anosmia.

He asked the experience of the Fellows in regard to the efficacy of the galvano-cautery treatment as a preventive or a cure for hay fever.

Dr. C. E. Sajous, of Philadelphia, stated that in the early part of his experience with the galvano-cautery he had a number of favorable cases. Last year he met with a number of unsatisfactory cases. What it depended on he did not know. Although all the cases were benefited, absolute relief followed in less than forty-five per cent. Some of the cases treated two years ago, and which escaped the attack the following year, had a recurrence last year. Some of the cases have entirely escaped. One case treated in 1881 with glacial acetic acid has had no recurrence.

Dr. Carl Seiler, of Philadelphia, thought the failures of the treatment of hay fever might be explained by the suggestion thrown out in the paper read, that the Schneiderian membrane is not the only source of irritation of the vaso-motor nerves. The source of irritation may be situated in the pharynx or in the larynx. If the case does not yield to treatment of the nasal membrane we should look further.

Dr. Samuel Johnston, of Baltimore, read a paper entitled

A CASE OF NASO-PHARYNGEAL GROWTH.

A child was brought to him on account of difficulty in breathing through one nostril. Examination showed that there was a tumor filling up the posterior part of the right nostril. After a short preliminary treatment the attempt was made to remove the growth with the écraseur. A spray of a four per cent. solution of cocaine was employed. A cord was first passed through the nostril and brought out of the mouth, so that, if necessary, the nostril could be plugged without delay. The wire of the écraseur was applied without difficulty. When the growth had been cut through about two-thirds, the shaft of the instrument broke, leaving the wire and about three-fourths of an inch of the instrument attached to the growth. An attempt was made to apply a second écraseur, but this failed. After trying to remove the portion of instrument broken off, it was decided to wait a short time and allow the growth to slough off. Four days later the attempt to apply an écraseur was again made, and succeeded without difficulty. The tumor measured one inch and a half in diameter, and was fibroid in character.

Dr. C. C. Rice, of New York, read a paper on the question

WHAT CASES OF NASAL CATARRH REQUIRE SURGICAL TREATMENT?

Almost every nasal chamber will exhibit irregularities and abnormalities of some kind. The introduction of more improved methods of determining the locality of inflammation has led to a more frequent resort to surgical measures. With the galvano-cautery almost any effect from a slight stimulation to destruction of tissue can be obtained. Those who condemn this instrument should state what use of it they object to. Not every case of anterior hypertrophy should be operated upon. The erectile tissue in this situation serves a valuable physiological function in swelling up and excluding irritating particles from the lungs. In determining whether or not an operation is required, the sensations of the patient should be taken into consideration with the results of the examination. If, after the use of a four per cent. solution of cocaine, sufficient hypertrophy to interfere with breathing is still apparent it should be removed.

Dr. F. H. Bosworth, of New York, thought that the so-called erectile tissue is not a true erectile tissue. There is no physiological function observed by its swelling up.

He also states that all persons will present abnormalities of the nose. He thought it a mistake to suppose that we have morbid conditions in every nose. The healthy nasal cavities present a typical appearance.

Dr. J. N. Mackenzie, of Baltimore, said that the microscope shows that the erectile tissue of the nose corresponds with the erectile tissue in other portions of the body. He believed that these bodies serve the physiological purpose of excluding irritating bodies from the lower respiratory tract. Experiments with horses driven through a cloud of dust have shown that while the anterior portion of the nose was filled with dust none passed into the larynx.

The President remarked that in man the nasal chambers are exceedingly degenerate. There is no animal in which the nose is so small in comparison with the rest of the face as in man. It is well known that structures which are passing through a process of degeneration are exceedingly variable. So it is with the human nasal chambers.

Remembering this fact, we come to another of great interest, that all animals with short faces, as the rabbit and cat, have on the nasal septum erectile bodies. He held that the object of these bodies was obstructive, and that by swelling up they protected the portions behind. If that is the case I do not see why we cannot claim that erectile tissue exists in man. It is my opinion that erectile tissue does exist, and is protective and obstructive.

The following papers were read by title: "Inflammation of the Antrum," by Dr. Beverley Robinson, of New York; "Additional Notes on a Case of Erysipelas of the Larynx," by William Porter, M.D., of St. Louis.

A vote of thanks was tendered the Philadelphia College of Physicians, the Union League Club, the University Club, and the managers of the Pennsylvania Hospital for courtesies extended.

The Association then adjourned.

The Rhythm of Fever.—Dr. P. D. Carpenter, of Pittsford, writes: "In your comments on the 'Rhythm of Fever,' in The Medical Record of March 20th, you say: 'Our correspondent forgets that in a chill both the temperature of the body and the heat-production are increased, though heat excretion is temporarily lessened.' In the latter part of the paper that I sent you, there was a quotation from an editorial in The Record, which says: 'There may be a fever, viz., its essential symptom, elevated temperature, when the actual heat-production is less than normal, provided heat-dissipation is also at the same time less.' In a chill the heat-dissipation is certainly lessened, and if heat-production were not also lessened, it seems to me that the accumulation of heat would be so great as to be incompatible with life, as perhaps may occur in fatal cases of 'congestive chill.' I think your objection loses its force when placed by the side of the quotation I have made from you."

Antipyrin in Phthisis.—Dr. Hoedmaker, of Davos Platz, has made numerous observations of the effect of antipyrin on patients with phthisis, and comes to the conclusion that they are more comfortable without it, although it certainly reduces the fever. He states that he has found salicylic acid, especially when combined with arsenic, of the greatest utility in the disease.

SYPHILITIC PACHYMENINGITIS AND PERIPHERAL NEURITIS —DISTILLED WATER AS A SOLVENT OF RENAL CALCULI — THE ALBUMENS OF THE URINE — DIPLOMAS IN SANITARY SCIENCE — HOSPITAL ACCOMMODATION FOR JEWISH PATIENTS.

London, May 24, 1886.

At the last meeting of the Pathological Society, Dr. Hale White showed some specimens of peripheral neuritis and syphilitic meningitis which presented some features of interest. They were taken from a woman, fifty-two years of age, who had been a hard drinker in addition to suffering from syphilis. For some months she had had occasional right-sided attacks of convulsions. When admitted into Guy's Hospital the patient seemed partly demented. The right arm was wasted, rigid, and contracted, and the right leg similarly affected, though in a less degree. A few days after admission the patient was attacked with right-sided epileptic seizures. In the course of seven hours no fewer than sixty-three attacks occurred. The face was affected and the patient was unconscious. The temperature rose to 103°, and the patient died eighteen hours after the last fit. Post-mortem, syphilitic ostitis of the back part of the frontal bone on the left side was found, and, adjoining this, characteristically syphilitic pachymeningitis, composed partly of fibrous tissue and partly of gumma. The digital nerves showed the changes described by recent workers as occurring in peripheral neuritis. The fibrous sheath round the nerve was thickened and sent in septa between the nerve-fibres. The latter were much degenerated, and in many no axis cylinder was to be found, all that could be seen being the granular material into which the white substance of Schwann had become converted.

At a recent meeting of the Clinical Society Mr. Pick, of St. George's Hospital, related a case which showed in a very striking manner the benefit to be obtained in some cases of renal calculus by the "distilled-water treatment." The patient was a man, aged forty-five, who, when first seen by Mr. Pick, was suffering from renal colic. From the symptoms and signs Mr. Pick was able to diagnose atrophy or absence of the opposite kidney, and the former condition was found at the autopsy. The patient was ordered to drink half a gallon of distilled water daily. After a week of this regimen he was suddenly seized with an intense desire to micturate, and passed nearly a gallon of urine in a very short time, and with it three small calculi. His symptoms were at once relieved, and in a week or two he expressed himself as feeling well. He remained so for a year, and then, after two attacks of renal colic, had suppression of urine, and died in six days. Although the ultimate issue was a fatal one, the marked and lasting (for a year) relief following the copious imbibition of distilled water was, to say the least, very noteworthy, and should encourage further trials of that mode of treatment.

At the last meeting of the Harveian Society a paper on "The Albumens of the Urine" was read by Dr. Robert Maguire. Some novel ideas were put forward. Hitherto serum-albumin has been regarded not only as the most important, but also as the most frequent form of albumin occurring in the urine. Dr. Maguire, however, has found globulin to occur far more frequently than has been thought. He has found it frequently in albuminous urine, both alone and together with serum-albumin. When the two occur together he thinks the amount of the globulin is always in inverse proportion to the gravity of the case. In grave cases but little globulin is detected, the albumen consisting almost entirely of serum-albumin. On the other hand, in the so called "physiological albuminuria" he finds only globulin. Dr. Maguire's explanation of the occurrence of one or the other of these forms of albumen is the following: Viewing albuminuria as due either to circulatory disturbance or to renal textural change, he suggests that where the nutrition of the glomerular epithelium is merely impaired, but no structural change has taken place, the more diffusible globulin passes; where actual structural change in the epithelium has occurred, the serum-albumin can no longer be kept in, and passes into the urine. The globulin is to be detected either by saturating the urine with magnesium sulphate in the cold, or by diluting the urine with a large quantity of water. In either case the globulin is thrown down. The latter test can be applied on a small scale by pouring a few drops of urine into a test-tube full of distilled water. After filtration the filtrate can be tested with nitric acid for serum-albumin in the usual way.

For several years past diplomas and certificates in sanitary science have been issued by the universities and other examining bodies. By a strange anomaly, however, their holders have been unable to register them. This injustice is to be remedied in the Medical Bill now before Parliament.

The London Hospital is at present, I believe, the only hospital which provides special accommodation for Jewish patients. The Metropolitan Free Hospital is about to follow suit. In their new building one-fourth of the total number of beds is to be set apart for Jewish patients.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 30 to June 5, 1886.

BAXTER, J. H., Colonel and Chief Medical Purveyor. Ordered to proceed to New York City on public business, and on the completion thereof to return to his station. S. O. 128, A. G. O., June 3, 1886.

PAGE, CHARLES, Lieutenant Colonel and Surgeon. Granted leave of absence for one month, with permission to apply for ten days' extension. S. O. 55, Department of Missouri, June 1, 1886.

GARDNER, E. F., Captain and Assistant Surgeon. Ordered for duty at Madison Barracks, N. Y. S. O. 49, Division of the Atlantic, June 1, 1886.

ADAIR, G. W., Captain and Assistant Surgeon. Granted leave of absence for two months, to take effect when his services can be spared. S. O. 128, A. G. O., June 3, 1886.

ROBERTSON, R. L., First Lieutenant and Assistant Surgeon. Relieved from temporary duty at Fort Snelling, Minn., and ordered to Fort Keogh, M. T. S. O. 45, Department of Dakota, May 24, 1886.

PHILLIPS, JOHN L., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Keogh, M. T., and ordered to Fort Sisseton, D. T. S. O. 45, Department of Dakota, May 24, 1886.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 5, 1886.

SMITH, HOWARD, Surgeon. Detached from the Nipsic and placed on waiting orders.

THE TREATMENT OF DIPHTHERIA.

BY S. HENRY DESSAU, M.D.,

The treatment of diphtheria has been [illegible] the most practical portion of the subject for consideration, while at the same time much that can be said under this head will have reference besides to the etiology and pathology of the disease. Diphtheria is a disease that is so familiar to all, that the consideration of any method or means of combating it must prove, I take it, full of interest. While it is my object to call attention to some points in the treatment of diphtheria that have been of material assistance to me in managing this uncertain affection, I shall not pretend to offer anything that I can claim as strictly original.

Perhaps the first question that may engage our minds is, Shall diphtheria be treated as a local or constitutional affection? Ever since the announcement to the medical world, by Oertel and others, that the disease depended upon certain germs for its causation, medical opinion has been somewhat divided upon the question. Unfortunately, however, bacteriology has not as yet been able to satisfy us altogether upon the matter, from the fact, as stated by Loefler, of Berlin, and other eminent authorities on the subject, that up to the present time the disease has not uniformly been successfully communicated to the lower animals. An immense obstacle has thus been placed in the way of further progress toward the solution of the question.

It has now been definitely settled, I believe, that the causation of diphtheria depends upon two varieties of germs, a *bacillus* and a *coccus*, but which of the two is the more important factor is left undetermined, simply on account of their imperfect communicability to the lower animals. This fact also leaves us in the dark as to whether these germs act upon the tissues involved in diphtheria locally or through the vascular system, so that Oertel has concluded it is first a local disease, and secondarily affects the general system.

But may we not seek in another direction for light upon the subject? The clinical history of disease in many instances, to my mind, furnishes valuable points in directing our thoughts in regard to treatment, and this, together with comparisons derived from analogy in other diseases, is certainly of great advantage. If we refer to erysipelas, for instance, to illustrate my meaning, we will find many features of that disease that may be compared with diphtheria. Here we know that it is a constitutional, self-limited affection, with a local manifestation that is likewise produced by a specific germ. I refer, of course, to idiopathic erysipelas. Then why may we not draw a like inference in regard to diphtheria?

In the early period of my practice I was in the habit of using both local and constitutional treatment in diphtheria, but experience has satisfied me that, with the exception of where the disease involved the larynx or nasal cavities, constitutional treatment was all that was required. In fact, the natural tendency of the disease being to cause a lowering and depression of the vital forces, the efforts to employ local applications in young children were found all the more harmful on account of oftentimes the most obstinate resistance on the part of the child. The result was, more exhaustion on the part of the physical forces, and more disgust and resistance on the part of the little patient when the time came for making the next application. Certain it is, in my experience, that my cases have done far better since I abandoned local applications.

I am fully aware of the argument that, after all, the remedies in most general use, such as the muriated tincture of iron, for instance, when used as a constitutional remedy, will also act topically on the mucous membranes of the pharynx, as it bathes them in the process of being swallowed. I grant this point, even at the risk of weakening my position as to the nature of the poison; but if this local application will suffice, it is an immense advantage gained for the little patient in his chances to resist the affection.

It has been stated by Oertel, as before mentioned, that the virus of diphtheria, having a predilection for the mucous membranes of the tonsils and pharynx, and the cavities of the nose and larynx in a milder degree, is first localized there as a point of infection, and, after producing its peculiar effects upon those parts, in the form of exudation, is thence absorbed into the system. Scientifically this may be admitted as a tenable theory, but, as I have before remarked, it should, notwithstanding, have little weight with us in directing our treatment against the disease, as we do not yet know how soon this secondary affection occurs. I have seen high fever, severe pain, and other clinical symptoms occur in diphtheria before the exudation was fully developed, and certainly I cannot believe that these were due to the slight amount of local inflammation present. For a long while my practice in the treatment of diphtheria was to administer the familiar combination of muriated tincture of iron and chlorate of potassium in solution only. But the elevated temperature at the onset of the disease was such a marked symptom, to my mind, that it occurred to me that an antipyretic that would not weaken the heart, while it would reduce the amount of blood-pressure, especially in localized parts, would possibly be of great assistance to the action of the iron and chlorate of potassium. Following out this idea I soon adopted the practice of administering tincture of aconite, in doses of a drop, or a fraction thereof, according to the patient's age, giving it every fifteen minutes for the first hour, and thereafter hourly. This, I found, tended speedily to reduce the temperature, so that in from twenty-four to forty-eight hours there was little or no fever present. Since this method of reducing the temperature was adopted I have had no occasion to regret it. On the contrary, with one exception, where the disease, though only involving the tonsils and soft palate, assumed a malignant character on the second day of its course, and destroyed the patient on the fourth day, the success with my cases has been uniform. Independently of the effect to limit the duration of the disease, and consequently the extent of the exudation, I believe many advantages are gained to the patient, in the way of promotion of comfort, as well as the relief of certain disagreeable features of the disease, as the vomiting, in the reduction of temperature. This is a point of great importance, in my estimation, in the management of diphtheria. The vomiting, for instance, in cases where the exudate has only involved the pharynx, not only adds to the exhaustion already exist-

[1] Read before the North western Medical and Surgical [illegible]

ing, but makes the condition of affairs doubly worse by not permitting either food or medicine to be retained, where the frequent administration of both is all-important.

It may be thought that aconite would have a tendency to further weaken the heart, already made liable to this unfortunate feature by the diphtheritic poison. The exact physiological action of aconite being still *sub judice*, this may or may not be. But in the dose that I have given, as my practice in the administration of this drug, I have seen no such effects as a weakening of the heart's action. On the contrary, I have every reason to believe that it strengthens the already enfeebled heart-action, as is shown by a reduction of the temperature and pulse. And through its action upon the vaso-motor nerves it certainly reduces blood-pressure.

Since the introduction of antipyrin a more reliable remedy for reducing high temperatures has perhaps been found, and will no doubt afford immense satisfaction to those disposed to follow this method of treatment in diphtheria.

In seeking for an explanation of the beneficial action, according to my experience, of antipyretics in diphtheria, with especial reference to those that do not too much weaken the heart's action, perhaps the best that can at present be offered is the fact, as demonstrated by Hamilton, of Edinburgh ("Pract.," vol. xxiv., p. 87), that exudations whether upon mucous or serous surfaces, or whether due to local mechanical obstruction in the capillaries, or certain changes in the condition of the blood, are the result of *suddenly increased blood-pressure*. The effect of antipyretics, like aconite and antipyrin, for example, when given in proper doses, is to lessen or modify this tension in the blood-vessels, either in a limited area or in the circulation at large, without at all weakening the heart's action. In diphtheria the blood, moreover, contains more albuminoids than normal, owing to the disorganizing influence upon it of the germ-poison, and the tension of the vascular system is increased suddenly, and perhaps maintained in this state for a prolonged period, through the irritant action of the altered condition of the blood, or the effect of the virus itself, as the case may be. There may also be mechanical obstruction in the capillaries of the tissues of the pharynx, due, it may be allowed, as stated by Oertel, to the ingress of germs occluding their lumen. The exudate already formed may thus be limited in its tendency to spread, or its appearance in other parts, as the larynx for example, prevented, by controlling or keeping within safe limits this sudden rise of blood-pressure. I might mention here in this connection that Hamilton, above quoted, regards croupous and fibrous exudation as due to the same local pathological mechanism, viz., suddenly increased blood-pressure, being manifestations of a difference in degree only, of the same. This is entirely independent of the view that the two manifestations may depend upon opposite and distinct *general* causes, and be recognized as distinct diseases. This view is corroborated by Wood and Formad, who, in their report on "Investigations of Diphtheria," say, that "any tracheitis of sufficient intensity," and it may be presumed from whatever cause, "is accompanied with exudation."

When I have the opportunity of seeing a case of diphtheria involving the pharynx or nasal cavities, in the onset of the attack, I am in the habit of administering a dose of calomel, say from three to five grains, according to the age of the patient, combined with from five to ten grains of bicarbonate of soda. This is given as the beginning of the treatment, for the purpose of clearing out the intestinal tract and inducing an increased action of the hepatic function. The importance of the latter will be mentioned further on. Besides tending to quiet the nervous system by relieving the intestines of any irritant substances that may be present, I believe the effect of the calomel and soda is often shown to aid in reducing temperature. The first dose, if effectual in emptying the bowels, is not repeated.

In common with the practice of most physicians at the present day, I use the tincture of the chloride of iron in combination with chlorate of potassium. The formula I prescribe is two drachms of the former to four ounces of a saturated solution of the latter, of which from one to two teaspoonfuls, according to age, are ordered to be given every hour. I do not regard this remedy as having any antiseptic virtue in the treatment of diphtheria, but as the tendency of the germ-poison is to cause a dissolution of the blood, I believe the iron in the form of tincture of the chloride aids in maintaining the normal condition of the hæmatoïdin of the red blood-corpuscles, while the chlorate of potassium, in moderate doses, exerts a similar action, and at the same time, in conjunction with the tincture of iron, induces a diuretic action which may, to a certain extent, aid in eliminating the poison, or the results of its action on the blood, through the kidneys. Besides this, it is barely possible that the combination exerts a beneficial action upon the stomach by preventing abnormal fermentation of its contents, and thus enables that viscus to perform its functions in a physiological manner.

This last-mentioned action of the iron and potassium is, in my opinion, not to be slightingly regarded, as we well know that the outcome of the action of the poison of diphtheria upon the blood is to cause depression and prostration of the vital forces, and whatever method can tend toward the maintenance of nutrition is of the highest importance.

Corrosive sublimate, in doses of one-fiftieth to a hundredth of a grain, repeated every hour, has been used by me in several well-marked cases of diphtheria with gratifying results. It was administered from the onset of the attack, where the pharynx and posterior pharynx were the seat of exudation, and, with the exception of aconite, was the only remedy used during the course of the disease. I am not inclined to regard the action of corrosive sublimate when used as an internal remedy as of an antiseptic character. Rutherford, in his investigations of so-called cholagogues, states that in small doses corrosive sublimate is a powerful hepatic stimulant in the dog, and supposes that it has a similar action upon man. Brunton, quoting Brieger, has lately shown that one of the important functions of the liver is its power to destroy ptomaines, or the alkaloid poisons produced in the ordinary process of digestion. Now, through the stimulant action of corrosive sublimate upon the liver, it is reasonable to infer that that organ may be made to assist largely in the elimination of the diphtheritic virus through its destructive action upon the same. This was what was referred to when mention was made of the use of calomel and soda, though, perhaps, in this respect the latter is the more important of the two.

Benzoate of soda and salicylate of soda, both of which have been recommended in the treatment of diphtheria, and in various cases used by me, have, according to Rutherford, a marked cholagogue action, though in a less degree than corrosive sublimate. Scarcely a less important matter than the consideration of drugs is attention to the general surroundings and diet in the treatment of diphtheria. I need hardly mention that good ventilation is of prime necessity. The temperature of the room should be kept at from 60° to 70° F., and the air rendered moist with a steaming kettle in the room. If possible a sunny exposure should be selected. Under every consideration the patient should be kept in bed until convalescence is fully established. The importance of this point will be recognized when we remember the extreme liability to collapse during the course of the disease, and to sudden attacks of syncope after all traces of exudation have disappeared.

As before mentioned, the natural tendency of the disease being to cause prostration of the nerve-forces, I order alcoholic stimulants, in the form of sherry wine or old whiskey or brandy, to be given at frequent intervals, from the beginning of the management of the case.

These may be given in milk in the form of a punch. The proportions I generally order are a tablespoonful of the whiskey or brandy to a tumblerful of milk; and of this a tablespoonful to a half-wineglassful may be given every two hours.

Milk and beef-extract should form the only articles of diet, the former being given in small and frequently repeated quantities, the latter not quite so often. In severe cases, where there is any disturbance of digestion, the milk is preferred in the pancreatized form; and the beef as sarcopeptones, according to the method of Leube. This insures their easy and speedy assimilation, and is worthy of important consideration.

In older children, where the pharynx is painful upon swallowing, I have found cracked ice held in the mouth near the pharynx, and allowed slowly to melt, prove very grateful. It is likely also to assist in reducing the local inflammation. Where the lymphatic glands of the neck become enlarged, applications of a weak tincture of iodine are used. So far I have made no mention of the use of local treatment, because I have ceased to use it except where the nasal cavities or the larynx are involved; and here it is not used for the purpose of destroying the poison in order to prevent its further infection of the general system, but merely in the first instances for purposes of cleanliness, to prevent, if possible, secondary septic absorption, as the nasal cavities furnish an unusual prone source in this respect. Where the larynx is involved, of course the idea is to get rid of the mechanical obstruction to respiration as soon as possible.

The application I prefer to use in the nasal cavities is a weak solution of biborate of soda, or common borax with boracic acid, to which a small quantity of glycerine is added. A more elegant combination, which also contains a small proportion of carbolic acid, is that known as Dobell's solution. This is usually applied in the form of a spray, from a Delano hand-atomizer, to the anterior nares, but an injection from a small nasal syringe may be in some cases preferable, and more effectively used according to the intelligence of the attendant. It should be used faithfully at least every two hours, and much oftener if the severity of the case requires it.

Where the larynx becomes involved, I have on one occasion met with most gratifying success in the use of the vapor of slacked lime constantly inhaled. The patient had erected over him a tent, from a blanket attached to the head-board of the bed and held up about its centre with a barrel-hoop. A bucket of lime, which was slowly slacked from time to time by pouring water gently over it, was kept on a stool by the side of the bed, and below its level under the blanket. This was used for forty-eight hours, together with hourly spraying of the pharynx, under at times considerable opposition from the patient, with lime-water to which a few drops of liquor potassa was added; trypsin has recently been favorably recommended for a like purpose, but I have had no experience with it.

Tracheotomy, of course, should be held as a *dernier ressort*. I have never had occasion to perform it.

And now, in conclusion, it might be said by some, as it has been said by Henoch, "in my experience all remedies hitherto recommended, and I believe I have tried almost all, with the exception of sulphur preparations, are entirely useless in severe cases of the disease, and these alone should be considered, since the milder ones recover spontaneously." In answer to such, I would say that my own experience has been more fortunate, for while I do not deny having lost cases of diphtheria, yet I have had some that were almost despaired of recover. Moreover, I deny that it is in the power of any physician to say in the early stage of a well-marked case of pharyngeal diphtheria, that it is a mild one and will recover spontaneously. I do not think that we are called upon to treat any disease more insidious in its progress than diphtheria, and cases that may appear to be mild when first seen are liable to end in the death of the patient. I well remember my own experience in such a case, having been previously recommended by a friend who stands eminent in the medical profession to abstain from all active interference in a mild case of the disease, as I would be able to convince myself of its spontaneous recovery and hence the uselessness of treatment. In the next case of the kind I saw, where the exudation was limited to the tonsils and the febrile movement not very strong, I followed the advice, and, much to my regret, the case went from bad to worse—the nasal cavities and post-pharynx became involved, and death followed from exhaustion. I regard every case of diphtheria I meet with, where the constitutional symptoms are marked, as of a serious character, or likely to become so, and treat it accordingly. As we well know, it is those cases which are so mild as to cause little or no anxiety that are so frequently attended with involvement of the larynx, and this danger should always be kept in view.

Neither do I entirely reject the view as expressed by Sir John Rose Cormack, in his article on diphtheria in Quain's "Dictionary of Medicine," that it is a disease that runs its own course and cannot be limited. But as in the treatment of other self-limited diseases, as typhoid fever for example, certain indications may be met that will sustain the vital forces and modify the intensity of the poison, so that *the tendency to death may be averted*. If I have succeeded in drawing your attention to any points in this short paper that may aid in accomplishing these two results, I shall feel that my labor has not been in vain.

THE PARALYSIS OF POTT'S DISEASE, AND ITS BEHAVIOR UNDER PROTECTIVE TREATMENT.

BY HENRY LING TAYLOR, M.D.,

AND

ROBERT W. LOVETT, M.D.

THE pathological condition of the spinal cord and its membranes in the paralysis so often accompanying Pott's disease of the spine has been so well described by Charcot, Michaud, Courjon, Echeverria, and others, that we can arrive at a fair idea of the lesion occurring in the spinal nervous system. We are, however, by no means so well informed of its predisposing causes, its clinical history, and its behavior under treatment.

It has been shown by these writers that the paralysis is very rarely caused by direct pressure of bone, as it is uncommon for even the very marked deformities to narrow the spinal canal to any great extent. Moreover, paralysis sometimes occurs before there is any deformity, it often recovers while the deformity gets worse, and many cases with extreme deformity are never paralyzed at all. Autopsy shows that in cases of paralysis the process ordinarily begins as an external pachymeningitis. The caries of the vertebræ, by contiguity or by irritation, causes this meningitis, and there is a deposit of inflammatory material in the dura, a consequent thickening of that membrane, and compression of the cord by this thickened dura at the point of irritation. The compression probably at once starts a myelitis, and it is this myelitis that is the cause of the paralysis. As the seat of the caries is in the bodies of the vertebræ, the meningitis is ordinarily anterior, and the myelitis is most severe in that part of the cord, especially at first, but it varies in extent from a mere infiltration to a complete disintegration of the cord. It may be more or less unilateral, it may extend up or down the cord, but pressure-myelitis causes the paralysis, which will vary with the extent and seat of the lesion. Ascending and descending secondary degenerations follow in time when it is of any considerable extent. If the myelitis recovers, it leaves a certain amount of sclerosis of the cord at the seat of the disease.

This, again, may be very slight, or the cord may be reduced to a fraction of its former size, and yet serve well enough to transmit healthy nervous impulses.

But meningitis is not the only cause of compression-myelitis in this disease, although it is the common one. There may be a direct strangulation of the cord by the vertebral arches, obliterating the canal; an abscess from carious bone may be a source of pressure within the canal; a caseous deposit from the vertebræ and a loose piece of bone have been found as sources of pressure. From the autopsies it seems probable that pressure from any source at once sets up a mild myelitis.

The clinical picture is what we should expect: a paralysis of motion, mild or severe, followed, if the case gets worse, by a paralysis of sensation, which is said by Courjon never to become complete. The motor paralysis varies from mere muscular weakness to complete loss of power. It begins as a sense of fatigue, a dragging of the feet; then there is inability to hold oneself erect. Unless the disease is in the lumbar region, the reflexes are exaggerated, and muscular spasms often start from the least irritation; they frequently appear spontaneous. The muscles are flaccid and the legs are powerless. With the secondary degenerations in the cord rigidity sets in; first the legs are rigid in the extended position, then flexion accompanies the permanent contracture. The bladder and rectum are paralyzed toward the end of all very bad cases, and whenever the lumbar enlargement is involved; in milder cases they escape. It is hard to explain why the arms are paralyzed in certain cases of dorsal caries, for an ascending secondary degeneration of the cord should give rise to no symptoms, and we have to assume an extended myelitis or meningitis. Of the sensory paralysis below the lesion there is less to be said: it is apt to begin as paræsthesia; anæsthesia afterward comes on to a greater or less extent, and when this occurs it means a pretty extended transverse myelitis.

Many cases of Pott's disease, especially in children, are bedridden, or at least non-ambulatory, without being paralyzed. When the disease runs its course unchecked, asthenia is often profound, and although there may be no trace of paralysis, the patient frequently has no desire or strength to walk or even to sit up. Another cause which sometimes keeps patients off their feet, independently of paralysis, is psoas contraction of a severe grade, especially if bilateral. Still another reason is a preponderating mental impression of inability to walk or stand. We remember a little girl whose disease was severe and active, where it was desirable that she should be kept off her feet for a time. This was much facilitated by an idea of the child's that she could not walk, which had been encouraged and probably suggested by her nurse, and the little thing was so impressed with the notion that she never made the attempt for months, although there was no trace of paralysis and she crept with facility. Here, as through the whole range of disease, we see function determined by the grade of consciousness of power, as well as limited by the degree of integrity of structure. Many cases persist in walking when paralyzed to a degree which ought to preclude it, and which would ordinarily do so, while others are bedridden with little or no paralysis, or remain so after the paralysis has totally disappeared, having recovered without being conscious of restoration. This accounts for the suddenness of invasion, and particularly of recovery, in some of these paralyzed cases.

We pass to the study and analysis of 59 cases of compression-paraplegia occurring in 445 cases of Pott's disease treated or observed by Dr. C. Fayette Taylor in private practice. In each of these 59 cases the paralysis was present at some stage of the disease. In 31 of the cases it had developed before the patients applied for treatment, while in 19 cases it came on while the patient was being treated, and in 9 cases it is impossible to say from the notes whether it appeared before or during treatment. With a very few exceptions the patients had had no mechanical treatment previous to applying.

Twenty-eight of the cases were males and thirty-one were females.

The age of the patients showed little of interest. The oldest was fifty years and the youngest two; 13 were adults and 15 were under three years of age. The location of the disease was as follows: of 59 cases, 1 was cervical, 7 cervico-dorsal, 37 dorsal, 7 dorso-lumbar, 4 lumbar, and 3 unclassified. The liability of the three regions (cervical, dorsal, and lumbar) to caries is about 1 : 5 : 3.[1] It will be seen from this that paralysis is more likely to follow caries of the dorsal vertebræ than disease of the other regions.

The character of the deformity was a most interesting point. It was classed as large in 20, medium in 10, and very small in 17; 12 were unclassed. With regard to shape, in 26 the outline of the deformity was rounded and very gradual, while in 16 it was markedly angular, 10 were classed as progressive, where the deformity became somewhat worse in spite of treatment. These 59 cases were by no means worse, so far as deformity goes, than any fifty-nine cases taken at random would have been. They were average cases; there was no one with any unusual amount of deformity, and its amount and character gave in advance no clew as to the likelihood of the occurrence of paralysis. To account for this seeming independence of the paralysis, we can only assume that the seat of the caries and its relation to the meninges is a more potent factor than the amount or character of the deformity.

A girl, twelve years of age, was admitted to Roosevelt Hospital, in 1872, completely paralyzed in the legs, which were rigid and beginning to flex on the pelvis. Ankle-clonus and increased patellar reflex were present; sensation was good, but had been impaired a month previous. No deformity was to be seen in the back, and the diagnosis of hysterical paralysis was made. The trouble had been coming on for six months, and no cause could be assigned for it. After six months of rest in bed, tonics, and electrical stimulation, she rather suddenly became able to stand and walk, and about this time a rounded projection was noticed in the dorsal region of the spinal column, and the diagnosis of Pott's disease was made. The deformity increased for a month or two, but under mechanical treatment, at a public institution, a cure was effected, and there has never been any return of the paralysis. Here, then, was a case of paraplegia occurring before deformity appeared, and of recovery from the paralysis while the deformity grew worse.

The paralysis occurred on the average about two years after the beginning of the disease. It came on immediately after a fall in 4 cases,[2] in 8 cases it appeared within one year, in 16 cases within two years, in 4 cases within three years, in 3 cases within four years, and 1 each in five, nine, eleven, fifteen, and twenty-eight years; 19 cases could not be classified. Its beginning was almost always gradual; it began oftenest on one side and was usually first noticed as a dragging of one foot, the other foot became involved in a few days, and the course went on as above described. In the majority of cases an unusual amount of pain in the chest and abdomen, even for Pott's disease, preceded the paralysis by some weeks, but did not ordinarily persist after the paralysis began.

It always began as a motor paralysis, and in a certain number of cases an incomplete sensory paralysis came on afterward. The latter is noted as having been present only fifteen times, but the number is undoubtedly too small on account of the impossibility of getting an accurate amount of past attacks. In some cases there was a complete paralysis of motion, with rigidity of the limbs,

[1] Location, Age, and Sex in Pott's Disease of the Spine. H. L. Taylor, Medical Record, Vol. xxx., No. 7, August 15, 1886.

[2] These traumatic cases are included in our study to draw attention to the great value of efficient protective treatment in severe spinal injuries, where the outlook is ordinarily so gloomy. Of the four, three developed Pott's disease—one of these recovered from the paralysis, and the two others were improving when last heard from; one case did not develop Pott's disease, but was completely cured of his paralysis by spinal support.

while sensation was perfectly good, and in other cases a sensory paralysis followed very closely on an incomplete motor paralysis. In 32 cases the paralysis of motion was complete, in 13 it was incomplete, while in 14 the notes were indefinite.

The duration of the paralysis in the cases which could be watched was never over three years, except in 1 case where the paralysis persisted after the lapse of six years somewhat improved. In 2 cases it lasted three years; in 5 cases it lasted two years; in 7 cases it lasted one year; in 4 cases it lasted from six to twelve months; in 8 cases it lasted six months; in 9 cases it lasted from two to four months; in 23 cases the duration was not known.

The average duration of all these cases was a little less than one year, and when the paralysis came on under treatment the average duration was only seven months. The disappearance of the paralysis was gradual—the sensory part recovered first, then the motor, and last of all the tendon reflexes became normal. In three or four cases the recovery followed in a few days or weeks on the evacuation of an abscess, and in 1 case the recovery was sudden and occurred during an attack of measles, after the paralysis had lasted two years. A recurrence of the paralysis was not uncommon, having occurred in 6 cases—4 patients had two attacks, and 2 others had three. The intervals between these recurrences varied from a few weeks to some years.

The tendency of the paralysis seems to be surprisingly strong toward recovery. Of the 59 cases analyzed, 39 are known to have wholly recovered; 3 recovered in part, 5 died of intercurrent affections, and the termination is unknown in 12 cases. That is to say, in the whole number of cases where the termination is known, eighty-three per cent. recovered wholly from the paralysis, and this percentage is undoubtedly too low; for, of the cases which died, 2 were recovering and 2 others were probably over their paralysis when they died, although they cannot be so counted. Of the deaths, 2 were due to pneumonia, 1 to acute phthisis, one to the opium habit, and 1 to acute cerebral meningitis. The termination is unknown in so many cases because they only came for consultation, or disappeared from observation after a little while, or were discharged for neglect. The bladder and rectum are noted as having been paralyzed in 8 cases, and here the per cent. of recoveries fell to fifty-seven where the result was known. The arms were affected in 3 cases—and of these, 1 wholly recovered and the other 2 partly. Muscular rigidity is noted in 5 cases, of which 2 wholly recovered, but it was undoubtedly present in many others. The latter symptoms mean much damage to the cord, and the wonder is that any recover from them. *Where the paralysis came on while the patient was under treatment* (19 cases), *the percentage of recoveries was one hundred in the* 17 *cases whose termination was known.* Of the 2 cases where the termination was doubtful, 1 was recovering power quite fast at the end of six months, and the other was still paralyzed when two years had gone by. Neither has been heard from since.

The treatment in all cases was directed to the spinal caries, and was protective, viz.: the application of the Taylor spinal apparatus, and chin-piece when necessary. Great stress was laid on thorough and adequate mechanical support entirely under the surgeon's control, and modified by him to suit the varying indications. The protection was only considered satisfactory when, with a firm and even impression of the pad-plates, the patient's acute symptoms subsided in a few days or weeks, his health and strength improved, and the progress of the deformity was substantially arrested without discomfort from the apparatus. The patient was put to bed and not encouraged to walk until there was a pretty complete return of power. There was no medicinal treatment directed to the paralysis.

It seems justifiable to assume from the statistics that in the course of a few months the paralysis will disappear without any other than the protective treatment for Pott's disease joined to rest in bed during the time of disability. Moreover, when paralysis occurs while the spine is being efficiently supported, our study shows that its duration is shortened, its type is milder, complications are fewer, and complete recovery from it is almost certain. Lastly, its rare occurrence during adequate mechanical treatment is to be noted. In these statistics it occurred only 19 times in 445 cases. Gibney[1] reported 62 cases in 295 cases of Pott's disease at the Hospital for the Ruptured and Crippled, of which perhaps a third were paralyzed before coming to the hospital. The French treatises deal with the disease as seen in hospital wrecks, and afford us no information as to its course or the frequency of its occurrence.

It seems, then, to be an affection of rare occurrence in Pott's disease under efficient protective treatment. It occurs without regard to the amount or character of the deformity, and is usually preceded by much pain; on the average it lasts a little less than a year. Its prognosis is extremely favorable in mild cases, or in severe ones if they can be treated early. If the bladder and rectum are involved, or muscular rigidity of long standing is present, the prognosis is not so good; but even then it is far from being bad. The treatment is efficient mechanical support to the spine and rest in bed. Under these circumstances it becomes a complication of spinal caries of no very serious import.

NOTE.—In order to make this paper as complete as possible we quote the following from a letter from Dr. C. Fayette Taylor, in Meran, Austria:

"You have chosen a good subject for your article, but it is probable that I could supply from memory the final results in some cases which failed to be recorded in the books. Cases that came paralyzed—long-standing cases, I mean—and cases that discontinued treatment after insufficient time and opportunity, ought not to be considered as having any bearing on the general results of paralysis under treatment by protection; for by protection is necessarily meant adequate protection, as to efficiency, time of beginning, continuing, and terminating it. Considered in this light, I am not aware that there was ever a case under my treatment, to whom protection was given at any time before the cessation of the destructive process, whether paralyzed at the time it came under observation or after, which did not entirely and permanently recover. In that connection some strange things have happened, leading me to believe that paralysis occurring during the course of disintegration of vertebræ is always in the first instance in consequence of the pressure of fluid, but that fluid-pressure does not produce permanent injury to the cord, merely suspending its function—that is to say, sufficient fluid-pressure to produce disintegration of the cord is not reached because the surrounding soft tissues give way first and the fluid escapes into the adjacent parts, thus diminishing the pressure on the cord. Hence the frequent occurrence of the appearance of a lumbar or psoas abscess and the recovery from the paralysis at the same time. More commonly, however, the retarded disintegration and diminished formation of fluid consequent on protecting the carious vertebræ allows the fluid to be absorbed and so lessens the pressure, when the cord resumes its function and the paralysis ceases. Permanent paralysis in consequence of Pott's disease, the evidence of my experience goes to show, is nearly always the result of bone-pressure from narrowing of the spinal canal—not often from exostoses, as is frequently claimed. The kyphosis results of course from destruction of several vertebral bodies. Even in the latter case, when the cord is bent at a sharp angle in a narrowed canal, there is good reason to believe that in some the cavity enlarges in time so as to give the cord more room, and its function becomes wholly or partly restored. This probability is forcibly illustrated in several cases of traumatism, where the paralysis occurred immediately.

[1] Journal of Nervous and Mental Diseases, April, 1878.

"D—— fell out of a third-story window and was taken up totally paralyzed in his lower extremities. I saw him nine months later. At this time his lumbar spine presented every appearance of an ordinary case of Pott's disease, several vertebræ being affected and the lumbar portion bulging outward in the ordinary way after loss of substance in the bodies. But there had lately been a gain of some motion in the lower extremities, which I attributed to enlargement of the spinal canal consequent on the softening of the bodies. He was walking about in a month and recovered rapidly and entirely under protection. The peasant here—mentioned in a previous letter—is another apparently precisely similar example, and seems likely to have a similar result. He was run over last July, and taken up paralyzed in his lower extremities. I saw him a month ago, and already there was slight power in one leg, though disintegration was evidently going forward in the bodies of the vertebræ, as indicated by the rational symptoms and the appearance of the projection in the back. If, as seems probable, there was dislocation or fracture by the injury in these cases, causing pressure on the spinal cord, we can only account for even the slightest improvement in its function by supposing a diminution of the pressure."

CYCLIC ALBUMINURIA.

By D. F. KINNIER, M.D.,

RANDOLPH, MASS.,

[illegible]

Cyclic albuminuria implies albuminuria in persons who appear to be otherwise healthy, local disease being probably present, but to an extent insufficient to produce any other symptom. This form of albuminuria is also spoken of as "albuminuria of adolescents," "intermittent albuminuria," and "physiological albuminuria."

It is very important that cyclic albuminuria should be carefully distinguished from the ordinary form of albuminuria due to morbid changes in the kidney, as the result of these two conditions is quite different, and hence, should a trace of albumen be found in the urine, it does not necessarily indicate serious renal disease.

Dr. C. von Noorden, of Giessen, classes physiological albuminuria into three groups: In the first group he finds albuminuria to be present in persons between the ages of puberty and twenty years, and especially in those of a feeble constitution, and rarely has he found this condition to be present in individuals above or below these years. In the cases which he examined he detected the albumen either while making clinical statistical researches, or during some slight ailment.

He finds the albumen to vary at different periods of the day. The urine is rarely albuminous the entire day. In these cases he found the conditions to be characteristic of physiological albuminuria, and quite distinct from the conditions present in any of the forms of nephritis. The urine is of a pale, clear color; the specific gravity varying from a high to a low, especially a high, specific gravity. The albumen generally coagulates on boiling. Globulin compounds and casts are rarely present, but when casts are present they are of the hyaline variety. Dr. Noorden finds the albumen to be most abundant about noon-time. In these cases of physiological albuminuria no renal disease has been noticed. Dr. von Noorden believes this form of albuminuria to be due to blood alterations, probably caused by slight renal disease rather than by changes in the tubuli uriniferi, as suggested by Leube.

In Dr. von Noorden's second class of physiological albuminuria there is present mucin, together with albumen; in this, as in the first class, albuminuria is most marked before noon. The mucin is supposed to be derived either from the lower urinary tract or from the kidney. In these cases the amount of albumen varies in proportion to the bodily exercise. Dr. Noorden believes this class represents mild vesical catarrh.

The third class, according to Dr. Noorden, is suggestive of slight catarrhal inflammation of the kidney, but not sufficient to cause renal disease.

In this class the albuminuria may continue the whole day and then disappear, or may be present about noontime and early in the evening, and disappear by bedtime. This class is noted for the absence of mucin, and the presence in the urine of casts, principally hyaline, with an occasional epithelial cast; now and then red blood-corpuscles are present.

Physiological albuminuria may exist when local disease is present, provided the latter is incapable of producing any other symptom. Within the past few years I have noticed several cases of this form of albuminuria. My attention was first directed to this condition while a student at Guy's Hospital, London, by reading an article in the hospital reports by Dr. Moxon, on "Albuminuria of Adolescents." Since then I have made careful examinations of various specimens of urine of persons whom I supposed to be healthy, and have noticed at certain periods during the day changes taking place in the urine, or diurnal alterations in the condition of the urine.

It may seem strange, but still it is none the less true, for us to find, on examining a specimen of this kind of urine, it to contain a large quantity of albumen, while an examination of another specimen of the urine a few hours later fails to detect albumen; and this condition may continue day after day.

Dr. Pavy has noticed that what is observed one day is repeated with more or less exactness the following day. Such have been the conditions observed in my cases.

He considers these cases have a cyclic character belonging to them, and he has applied the term "cyclic albuminuria" to this form of albuminuria. I have examined the urines of both adults and children from early in the morning till late at night, and I have noticed that in the majority of cases the urine was free from albumen from 5 A.M. till 8 or 9 A.M., after which time traces of albumen were detected in the urine, and gradually reached its maximum about the middle of the afternoon.

A peculiarity of this form of albuminuria is that after reaching its maximum, it gradually declines, disappearing by bedtime as a rule. In some of the cases which I have examined, I have observed albumen in the urine as late as 10 P.M., but this is the exception rather than the rule; in the majority of cases the albumen disappeared from the urine by bedtime (10 P.M).

The amount of albumen present varies considerably, on one day being quite large, the following day the amount being smaller.

The time of day at which the albumen appears in the urine is quite regular; in some cases I have observed albumen to be present in the urine at 10 A.M. and 11 A.M., and on the following day the albumen appeared in the urine of the same cases between 10.30 and 12 M.

In all the cases which I examined I could find no evidence of Bright's disease.

The health of my patients was unimpaired, notwithstanding the fact that the presence of albumen was noted in the urine for months. A microscopical examination of the urine revealed nothing of importance with the exception of crystals of oxalate of lime.

In one or two cases the character of the pulse was very like that of Bright's disease, but the pulse as a rule was quite soft. Whether or not this form of albuminuria is to be regarded as an early stage of Bright's disease is a point yet to be decided.

My own cases presented no evidence which would lead me to suppose that anything serious should follow as a result of this form of albuminuria. No causal relation, according to present opinion, exists between this form of albuminuria and Bright's disease. In some cases the interval between the complete disappearance of the albumen from the urine until its return a second time,

varied from one to three months, and a careful examination of the urine in those cases where this form of albuminuria appeared for a second or third time, gave no evidence of the presence of Bright's disease, and on no occasion did I find casts of any description present in the urine. The form of albumen present in the urine in these cases is supposed to be serum and alkali-albumen.

The following cases best illustrate this form of albuminuria:

A. B——, aged twenty-four years, medical student, came to me January, 1886, suspecting something wrong with his kidneys. The next few days following the one he called on me, I asked him to carefully examine his urine after rising in the morning and while fasting, till bedtime.

He says he examined his urine carefully with nitric acid and heat, and other recognized albumen tests, all of which he says produced a decided milkiness of the urine, denoting albumen, which increased on standing, and at the end of twelve hours left a deposit of about one-twelfth per cent. albumen.

The urine was acid, specific gravity 1.022, no casts or sugar; a few crystals of oxalate of lime were seen upon microscopical examination of the urine. He came to me January 28th, and I examined a specimen of his urine, which was passed on arising and while fasting. I found no albumen. About noon of the same day, and at 5 P.M., I examined specimens of his urine, and I found albumen present each time, but most abundant at 5 P.M.

Examination of a specimen of urine at bedtime of the same day showed only the faintest trace of albumen.

Several days later I asked him to examine his urine early in the morning and through the day. He reports albumen present at 11 A.M., 5 P.M., absent at 10 P.M. The amount of albumen present he says was much less than on former occasions. The following morning I advised him to examine his urine before breakfast, and then to breakfast chiefly of eggs and fish, and note the difference, if any, in the condition of the urine.

As a result of the examination before breakfast, he reports albumen to be absent from the urine; examination of urine two hours after breakfast, or 10 A.M., shows the presence of albumen in small quantities; examination later in the day shows larger quantities of albumen to be present; albumen absent at bedtime, 11 P.M.

The urine passed on arising in the morning of January 30th contained no albumen, reaction acid, specific gravity 1.028; at 11.30 A.M. albumen present, acid reaction, specific gravity 1.023; at 5 P.M. the specific gravity was greater than at any other examination, albumen present in slightly larger quantity than at 11.30 A.M. At bedtime specific gravity 1.020, which was less than on any previous examination during the day; a trace of albumen present in the urine.

Examination of the urine for a few days later gave the same result apparently as observed on January 30th. Microscopical examination of the urine revealed nothing of importance, no casts, no sugar.

This patient had been informed that he had disease of the kidneys.

After he had been under my care for a few weeks I informed him the trouble was not what he supposed (Bright's disease), but the form of albuminuria now under consideration. A few days ago I saw this patient for the first time in several weeks; he said he had examined his urine carefully the past few days and found the albumen very decidedly diminished, and I informed him that I thought the trouble would eventually disappear.

Mr. J. T——, a healthy-looking young man aged twenty-three, came to me complaining of lumbar pain, and thinking his kidneys might be affected, brought a specimen of his urine to me, stating that he would like it examined carefully so as to relieve his mind of any doubt as to the nature of the disease if there were any present.

Examination showed albumen present, which caused him great anxiety. Thinking that the case was one of the class now under consideration, I desired him to bring me specimens of his urine passed at different periods of the twenty-four hours for examination.

Daily examination of the urine was made for several days. Examination of the urine passed on rising in the morning and while fasting showed albumen to be absent. The albumen sometimes appeared in the urine as early as 9 A.M., and again not until noon-time.

The quantity of albumen, though small in the morning, gradually increased through the day, reaching its maximum between 3 P.M. to 7 P.M., then gradually declining, the albumen either disappearing entirely from the urine or only a trace being detected in the urine at bed-time.

In this case there was no evidence of Bright's disease, heart normal, pulse soft and not characteristic of renal disease. Such was the condition of the patient when seen by me in the fall of 1884.

A few weeks ago Mr. J. T—— visited me and I examined his urine for several days, and found the urine still to contain albumen, but in a much less quantity than when he first came to me in 1884.

The albumen appeared at regular periods of the twenty-four hours on this as on previous occasions. The last examination, made but a few days ago, showed the amount of albumen to be very much diminished, and I gave as my opinion that the albumen would probably disappear from the urine.

I have to-day, April 24th, examined a specimen of his urine passed on arising, which contained no albumen; that passed later in the day contained albumen in varying quantities; that passed at bedtime contained no albumen. The urine passed between 5 P.M. and 7 P.M. contained the largest amount of albumen, but much less than on former occasions.

Mr. J. McC—— consulted me in the winter of 1885. He was a druggist and had learned how to test his urine for albumen. He said he was subject to albuminuria, but said he could detect albumen in his urine at certain periods of the day only.

He states that he cannot detect albumen in his urine on arising in the morning, but that he finds albumen by noon-time, which gradually increases through the early afternoon and evening, and gradually disappears by bedtime.

He says on some occasions he finds only a very small trace of albumen present in the urine, and at other times fails to detect any albumen.

I have made repeated examinations of his urine, and on the whole I find his statements to be quite correct. I last saw him in March of the present year, at which time I examined his urine carefully and found albumen present in so small quantities that I informed him the albumen had almost entirely disappeared from the urine.

Dr. Pavy believes that albumen may persist in the urine without giving rise to grave conditions, and says he has met with cases which bear out his opinion. The subject is worthy of careful inquiry.

THE PARISIAN MODE OF OPERATING FOR CATARACT.—De Wecker first washes out the palpebral aperture by a fine jet of solution of bichloride of mercury, 1 in 2,500, then makes his section with the thinnest possible knife, by means of puncture and counter-puncture. This done, he does not perform iridectomy, nor does he lacerate the capsule in the usual way, but bites a large piece out of its centre with a fine cystotome forceps. After pressing out the lens with the back of a curette, he injects a solution of eserine into the anterior chamber by means of a delicate drum-syringe, and one sees an immediate contraction of the iris to a pin's point, and a circular pupil. The eye is again carefully washed by a stream of bichloride, and then covered with a dressing of eserine, glycerine, and bichloride, which is changed daily. De Wecker assures me he has not had a suppuration this year.—*Cor. Cincinnati Lancet and Clinic.*

SOME SUGGESTIONS AS TO THE CARE OF THE INSANE PRIOR TO THEIR ADMISSION TO AN ASYLUM.

By HENRY A. HUTCHINSON, M.D.,

MEDICAL SUPERINTENDENT OF THE WESTERN PENNSYLVANIA HOSPITAL FOR THE INSANE.

THE care of the insane previous to their removal to an asylum is a responsibility demanding the wisest judgment and thought of those whose duty it is to be thus engaged.

In some of its forms no disease is more amenable to treatment in its acute or early stages, and no fact than this is more widely recognized by alienists and more earnestly advocated.

As the superintendent of one of our large State hospitals for the insane, I have had ample opportunity to observe the methods often employed in caring for this afflicted class, and from these observations I am inclined to believe the reason a larger percentage of cures is not obtained in hospitals consists in the ofttimes indifferent treatment patients receive before their admission.

In many families there exists a prejudice in committing patients to a hospital, and to commit one of their afflicted members to an institution of this character is regarded as a disgrace both to the family and to the patient.

A short time since a patient was brought to this hospital, and the mother, upon giving me the history of her daughter's case, remarked: "I have prayed Heaven to spare me this greatest of all afflictions, the disgrace of having a child a lunatic and confined in an asylum."

As a result of this prejudice many insane are treated at home by their friends, the objectionable lunatic asylum, with its every facility for the care of just such cases remaining an insurmountable barrier to the patient's rapidly departing chances of recovery.

When these endeavors have signally failed to restore the patient to reason, and the unfortunate being has become incurable and broken down in bodily health, he is taken to the hospital, and the friends accompanying him entreat the asylum physician to care for him kindly, and are surprised if an unfavorable prognosis be given. Many who have no friends to care for them, or in whom the insanity is of a dangerous type and unsafe to be cared for at home, are arrested and placed in jail, their period of residence varying sometimes but a few days, or extending for several weeks, until the court decides as to their insanity, and they are then committed to an asylum.

It is at this very time, upon the first manifestation of the disease, that the court should at once direct their admission to a hospital, as their residence in jail, where no means exist for their proper treatment, and, as is often the case, where they are provided with the barest necessaries of life, is the time when judicious medical treatment and the care and comfort of a well-appointed institution would effect their restoration to reason.

Female patients have frequently complained to me of the disregard of the proprieties of life during their imprisonment in jail prior to their removal to an asylum. No jail should be conducted without a matron, whose duty should be to care for the female inmates.

Of forty-five patients committed to this hospital by order of the court, of the thirteen counties comprising this asylum district, sixteen were committed directly from jails, and of this number but three recovered, though a large proportion were acute cases.

A no less important factor in the care of the insane is the time and manner of their removal thereto. The larger number of patients when admitted to our hospitals are in poor bodily health, and there can be no doubt the condition of many is made worse by the fatigue and exposure incident to the journey. In acute cases the exhaustion following is often fatal. In this hospital fifty-nine deaths occurred during the past year, eight died whose period of residence was but twelve days, and two were in a dying condition at the time of their admission, and died within seventy-two hours after.

One of these patients, suffering from acute melancholia, was in a state of collapse when admitted; the other, who had typhoid fever, was beyond the aid of all human skill when brought to the door.

Female patients should always be accompanied by some female friend or relative in whom the patient has confidence, and to whom she can make known her wants and necessities. The total disregard of these proprieties, as shown so frequently in female patients brought to asylums in the custody of men, and who are perhaps strangers, is often attended with great mental excitement, prolonging the insanity, and operating largely against possible recovery.

All superintendents will agree with me, I think, in regard to the difficulty in obtaining a history of patients admitted to their hospitals; so often the friends hesitate or dislike to state the particulars and etiology of the patient's trouble, thereby embarrassing the physician in his future treatment of the case, and also acting as a hinderance to the patient's recovery.

The hesitancy on the part of friends, however, seems universal, as the records of this institution prove.

In preparing this paper I have referred only to what appears to me to be the more prominent defects in the present methods of providing for this class of humanity, but I feel assured, that "until the present laws controlling the admission of patients are amended, making provision for the overcoming of these evils, the mortality in the State hospitals will be necessarily large, and the number of cures materially lessened."

HÆMATOMA AURIS.

THREE CASES TREATED BY THE CONJOINED USE OF MASSAGE, GALVANISM, AND LEECHING.

SERVICE OF CHARLES H. NICHOLS, M.D., LL.D.,

MEDICAL SUPERINTENDENT OF [illegible] ASYLUM.

(Reported by SANGER BROWN, M.D., First Assistant Physician.)

CASE I.—Puerperal mania in a lady, aged thirty, commencing quite suddenly about ten days after her first confinement. First appearance of tumor was noticed in left ear about three months later, and about three days after a change of the manifestations from a comparatively mild to a very active type. Galvanism was used once, and massage from four to six times, daily for three weeks. Two days after the tumor was noticed in the left ear, one was observed to be making its appearance in the right, and this, too, was treated in the same way. Both tumors continued to enlarge slowly for about five days, and then remained stationary for about the same, or perhaps a somewhat longer period, when they began slowly to subside.

In the left ear the tumor, when largest, was about the size of a medium-sized almond; in the right it was about two-thirds that size.

The patient was discharged, recovered, after having been in the asylum eleven months and sixteen days, and at that time only a very slight trace of deformity could be detected in the left ear, and none in the right.

CASE II.—A very active type of acute mania in a highly refined and cultivated single lady, aged thirty-two. Hæmatoma appeared in both ears about six weeks after her admission, and about ten weeks after the appearance of mental derangement. In this case the hæmatomæ were not immediately preceded, accompanied, or followed by any noticeable change in the insane manifestations, the patient having been very actively excited throughout.

The same treatment was employed as in Case I., but the tumors increased in size much more rapidly; and, unfortunately, by means of some apparent defect in the battery used, on the fifth day of the treatment the galvanic current was applied with such strength as to thoroughly blister both ears. This accident prevented further interference for several days, but meanwhile the growth of the tumors appeared to have been

arrested. Leeches were next applied daily for four days, and about ℥ ij. of blood taken on each occasion; and at the end of this time galvanism and massage were increased, and continued two months. Massage alone was practised somewhat irregularly for a month later.

In this case the tumors, when largest, involved nearly the whole upper three-quarters of the auricles, and were about a half-inch in thickness.

The patient was discharged, recovered, seven months and nine days after her admission, with no more deformity than a slight thickening of the ears without obliteration of the normal lines.

Case III.—Puerperal mania in a young married lady, twenty years of age, confined with her first child.

Hæmatoma appeared in the left ear in the fourth month of her disease, which until five days prior to the appearance of the tumor had been characterized by noisy incoherence and a tendency to destructiveness and violence; but at this time she became very silent and stupid, the features indicated almost complete mental stagnation, and the secretions of the mouth and nose were utterly neglected.

The same treatment was instituted as in Case I., with the addition of leeching every alternate day for the first eight days. No increase in the size of the tumor could be noticed after the first week, and it had perceptibly begun to diminish before the end of the third week.

This patient is still under treatment, having been admitted upward of six months ago, and in her case there is nothing that could properly be called deformity.

In none of these cases could it be fairly supposed that the hæmatomæ were the result of traumatism.

A great deal of time and attention is necessary on the part of the physician in order to apply the above treatment thoroughly, but it is to be hoped that someone in a position to do so will apply it to a greater number of cases than I have done and report the results.

In those very active cases, where the tumor reaches the size of a hen's egg within forty-eight hours after its first appearance, it may well be doubted if much can be done to arrest its development or relieve the deformity.

Clinical Department.

VERTIGO, AND ITS TREATMENT BY BLISTERS.

Dr. Charles E. Willard, of Catskill, N. Y., writes: "Having had under my professional care during the past winter an unusually large number of cases of stomachal vertigo, I feel constrained to place upon record some of them, as they differed somewhat in their most prominent symptoms from those usually recorded as classical. I hope that that which caused me much vexation of spirit will prove of service to some other members of the profession who, like myself, have been driven to the wall by these often stubborn and intractable symptoms.

"To be brief, then, I will begin at once with some of the symptoms as witnessed in Mr. J——, aged forty-two. The first attack occurred while upon a ladder. The sensation, as he graphically described it to me, being as though an earthquake was about taking place, the house and the ladder moving as though on the waves of the ocean, rolling and pitching, but always with the roof ahead, and never turning sideways; a sensation of fear, and a peculiar sick or faint feeling at the pit of the stomach; the knees also appearing to lose all their strength; during all this time he was conscious there was no earthquake, or that the house was anything but standing firmly. His arms were not affected by the general weakness, and by holding himself closely to the ladder he avoided falling; and in a short time, the symptoms passing off in a measure, he was enabled to safely descend the ladder. There were no further developments that day; but the next morning, upon awakening and turning upon his left side in the bed, he immediately had a return of the dizziness, only this time the bed seemed to go pitching around the room, always the foot of the bed first (ahead), as though it were floating rapidly upon a huge wave of water, never turning over or upon its side, but always remaining level. After resting for a while upon the back the symptoms in a measure subsided, but upon again turning upon the left side there was a reappearance of all the symptoms just described, with the addition, this time, of a shower as of black soot falling before the eyes. All subsided again in a short time by turning upon the back, and after taking a short nap he carefully turned upon the right side and was enabled to get up, slowly dress himself, and eat a light breakfast. During the next ten days these symptoms occurred at irregular and uncertain intervals, accompanied by headache of a peculiarly distressing character, completely preventing any kind of labor, either physical or mental; there was some slight hesitancy in the speech; great mental depression, as though upon the border of some impending evil; during this time walking was very uncertain; upon making any effort to turn to the left he was likely to fall, or stagger off of the sidewalk into the street. Whenever it was necessary to turn a corner to the left, it was necessary to walk to the end of the curb, make a slow and complete circle to the right the whole width of the sidewalk, and then go ahead again.

"In another case, Mrs. W——, the symptoms followed an attack of erysipelas, and for two days and nights there was frightful headache, the patient remarking as though her head was in a vice, the pressure being upon each temple. During these forty-eight hours there was constant nausea, with frequent vomiting and retching, nothing but froth and mucus coming from the stomach, as there was no food taken during this time, the pain meanwhile being most severe upon the right side of the head. The patient was confined to the bed ten or twelve days. The dizziness was so great that she could not sit up, even in the bed, without producing faintness and vomiting. During all this time there was a constant roaring in the head as of a waterfall, a ringing in the ears, more especially the right, together with pain, and before each eye a large wheel, revolving rapidly, with broad spokes with deep notches between, the wheels apparently approaching each other and then receding constantly. Upon looking up she could read the print in a newspaper, but upon looking down everything was a blot and dizziness.

"This case, unlike that of Mr. J——, had a recurrence of the dizziness upon looking or turning to the right, even lasting some days after she was able to be moved from the bed. There was a constant and severe pain at the back of the neck, more especially upon the right side, together with a fulness and throbbing which could be seen and felt; the pain extended down the whole length of the spine, and alternated with the dizziness. When the head was most dizzy the pain in the back was less severe, and *vice versa*.

"In another case, that of Mrs. H——, the dizziness was always accompanied with a dull, aching pain in the left lung. The pain did not interfere with the breathing, and upon auscultation the lung was found to be free from disease of any kind. The pain in the lung always disappeared with the dizziness. In this case the patient was often awakened suddenly in the night, the dizziness and pain already present, when the bed, room, and furniture would apparently be pitching about in the greatest confusion. These distressing symptoms would last from one-half to one hour and then subside, leaving a peculiar feeling in the head not to be described, with soreness and pain, as though from some severe side pressure. This also would wear off in the course of twenty-four or forty-eight hours, sometimes, but not always, followed by vomiting. During the continuance of the symptoms no food could be taken or retained by the stomach.

"In another case, that of a gentleman, Mr. H——, aged

fifty-five, the attack would occur so suddenly that on several occasions he fell upon the floor, and was unable to arise for some time. I might go on and mention a number of other cases, each having some peculiarity of its own in common with the general symptoms, but I have already exceeded the original limit of this paper.

"Now for the treatment. After trying the various remedies recommended in the text-books, and not deriving the results I desired, I applied *blisters* to the *neck*, and in some cases, when the pain in the back was severe, all the way down the spine. The result of the blistering was very satisfactory, improvement beginning almost immediately, and my patients are to-day attending to their ordinary duties. Of course I did not neglect but continued general treatment. I think that the use of blisters in these cases cannot be too highly recommended, even though we cannot explain their *modus operandi*. In the treatment of these cases I used a *blister* which does not contain cantharides, and therefore is free from the exceedingly unpleasant complication of strangury. These blisters, or 'issue plasters,' as they are called, have proved very satisfactory in my hands, not once producing an unpleasant symptom—they blister quickly, without pain of any consequence, and by returning them to the blistered surface an issue can be kept up for any desirable length of time—and, as I remarked above, without the slightest fear of strangury occurring as a complication. I greatly fear that with the general practitioner the beneficial effects of judicious blistering, in these and other similar cases, is oftentimes lost sight of in dread of the unpleasant symptoms produced by cantharides."

THE ETIOLOGY OF HÆMATOMA NEONATORUM.

Dr. John Parmenter, of Buffalo, writes: "The synopsis of Dr. Küstner's views upon the etiology of hæmatoma in the new-born, published in The Medical Record (May 15th), induces me to mention a case occurring in my own practice, some eighteen months ago, which seems to support this theory. The child was of average size, and was born three hours after the beginning of regular pains. The labor was very easy, requiring no external aid of any kind. Almost immediately after birth a tumor developed over the sterno-cleido-mastoid muscle, and soon reached such proportions as to occasion severe dyspnœa. This condition lasted for about one week; after which time absorption began, causing the disappearance of the tumor in about three weeks. The child died some months later of entero-colitis. The total absence of any force in the delivery of this child leads me to regard Dr. Küstner's torsion theory as a very probable one."

SUDDEN DEATH FOLLOWING EXCISION OF THE UVULA.

Dr. W. W. Tompkins, of Charleston, W. Va., reports the case of a negro, thirty years of age, who asked his advice on account of a constant tickling in the throat and slight difficulty in breathing. Examination showed the uvula greatly elongated and projecting down below the base of the tongue. Its removal was advised, but the patient said he was afraid of an operation, and accordingly a gargle was prescribed; later in the day, however, the patient sent for Dr. Tompkins, and requested him to cut off the uvula. A small portion was accordingly removed, and the patient expressed himself as feeling better. In a few minutes the man's room-mate ran into the doctor's office and said the patient had dropped dead. There had been but little hemorrhage, and the operation had seemed to relieve the symptoms. But the patient had, on the occasion of his first visit, said that he had heart disease, although, as he was wet and dirty, having worked at ditching all night, no physical examination was made. Dr. Tompkins had thought of giving ether, as the patient was so nervous and fearful, but congratulated himself afterward on not having done so. Death was evidently due to cardiac disease, the immediate cause probably being the excitement caused by the operation. The patient's father had dropped dead under somewhat similar circumstances three years before.

A NEW METHOD FOR THE REMOVAL OF INTRAMURAL UTERINE TUMORS.

Dr. O. Stroinski, of Chicago, writes: "After severe losses in removing intramural uterine tumors through the abdominal or vaginal walls, I decided either to abandon entirely any attempts of extirpation of these tumors, or to find a method that would give a reasonable show of favorable results. Lately I have found that continued intra-uterine injections with diluted subsulphate or sesquichloride of iron produce a discharge of mucous membrane, as well as of muscular stratum, and that, combined with the effect of contractions always evoked by these injections, causes the intramural tumors to be forced into the uterine cavity, where they may easily be seized and extracted. I will give the minute details of these proceedings at another time, and will now merely formulate the conclusions which I have arrived at after a careful study and a good deal of experience: 1, Extirpation of intramural uterine tumors through the abdominal or vaginal walls is as unnecessary as it is dangerous; while, 2, there are certain procedures which always transform the intramural into an intra-uterine tumor which can be easily extirpated; 3, these procedures only should be made use of in the removal of intramural tumors, being entirely harmless, and never endangering the life of the patient nor maiming the sexual organs; 4, even the largest myoma might be easily removed by this operation; 5, only tumors situated on the surface of the uterus are excluded from this procedure. I have operated on cases in which large doses of ergot had been taken for a long time without the slightest effect, and in one case in which the tumor had existed before marriage and a child had been born without the tumor losing its size or changing its position. I will furthermore say, that I have operated in private as well as hospital practice, so that there cannot be any doubt of the reality of the facts."

COCAINE IN SEA-SICKNESS.

Dr. Charles F. Mason, Acting Assistant Surgeon, U.S.A., writes: "In a recent trip from New York to Norfolk by sea, I had an opportunity of observing, both in myself and others, the remarkable curative effects of cocaine in sea-sickness. The cases treated, four in number, were all adults, two being physicians. The symptoms in all were extreme nausea and great depression; no vomiting. Cocaine hydrochlorate, in doses of twelve minims of a four-per-cent. aqueous solution, afforded almost complete relief in from fifteen to thirty minutes, so that the three patients who were below were enabled to dress and come on deck. After a second half-grain dose (two hours' interval) the relief was complete and permanent."

A CASE OF TEMPORARY AMNESIA.

Dr. George White, of Chicago, writes: "Apropos of the case of temporary cerebral 'absence' of the stenographer in the late Chicago, Rock Island & Pacific Railroad train robbery and murder of the express messenger, I have to report a somewhat similar case. It may be of some psychologic interest. On April 12, 1886, I was hastily summoned to 1515 West Monroe Street, this city. There I saw a boy, ten years of age, apparently laboring under acute mania or aggravated hysteria. The case was characterized by delusions and hallucinations; incoherent speech; laughing and crying at regular intervals;

submissiveness and violent attempts to injure others alternating; pupils dilated; no elevation of temperature; motions at irregular times inco-ordinate; passage of urine free; bowels regular. No depressions or injury of any kind about the head could be found. There were no injuries received at any time, so far as I could learn; no falls; in fact, the evidence as to injury was negative in every way. Pressure along the spine elicited no tender points, but bilateral pressure at the third lumbar vertebra caused the knee-joints to yield. Prepuce abnormally long and adherent entirely around the corona glandis, and attempts to minutely examine the malformation were met by violent resistance. He never had any trouble with the urinary organs, and the parents had never noticed this peculiarity till I called their attention to it. He had always enjoyed good health hitherto, and the present trouble seemed instantaneous in development. No nervous history in family aside from slight hysteric attacks in mother and chorea in an aunt on the mother's side of the family. The father claimed invariable good health; rest of family in good health. I ordered chloral hydrate and bromide of potassium, and the next day was surprised to find my patient much better. On the third day he was entirely well—the pupils were normal; there was no response to lumbar pressure, and the mind was perfectly clear. Again seeking for the origin of this peculiar set of phenomena, I learned that as the boy was returning from school, at noon, a dog jumped at him, but did not bite. The scare was followed by unconsciousness in five or ten minutes after reaching home. His memory was blank as to the events of the afternoon and night of that day. Up to the present time he is as healthy and mentally as bright as the rest of the children."

HYDROGEN PEROXIDE IN DIPHTHERIA.

Dr. William B. Clarke, of Indianopolis, writes that he has seen such wonderful results follow the use of hydrogen peroxide in diphtheria that it would be hard to induce him to use any other local remedy in that disease. After its application to the false membrane, the corroding effect is so great that the mouth and nose are filled with the froth. The membrane is quickly dissolved and easily expelled.

LACK OF DEVELOPMENT IN A FEMALE SEVENTY-SEVEN YEARS OF AGE.

Dr. F. O. Manning, of this city sends us the following case: He was called to see an old woman aged seventy-seven, but on his arrival found her dead. The woman was the size of a child aged eleven, though her face was that of an aged person. She had been failing in health for the past three or four years, but had retained her faculties until within the past two years, when she had become demented. During the past few months her skin and its appendages had become extremely sensitive, and any attempt on the part of her relatives to cut her nails excited a violent fit of screaming. Her height was four feet three inches. The hair was dark brown, and only very slightly tinged with gray, and had, before being cut, reached nearly to the floor. There was no hair on the pubes or in the axillæ, and there were no breasts nor even any sign of a nipple. On opening the abdomen, the spleen was found to be small and presented a granular appearance. The kidneys were situated a little higher than normal, and were very small, being no larger than would be those of a child aged eleven. They presented all the appearances of a long-standing nephritis, and the bladder was also the seat of a chronic inflammation. The uterus was very small, hardly larger than an infant's. The ovaries were in a very rudimentary state, and wholly undeveloped. The vagina was occluded at its lower portion, but was patent at its upper part near the uterus. The woman had never menstruated. The other organs were not examined, owing to the strenuous objections of the relatives.

Progress of Medical Science.

A Peculiar Fracture of the Malleolus.—Dr. Léon Le Fort describes, in the *Bulletin Général de Thérapeutique* of March 15, 1886, the following case: A young man, aged eighteen, slipped and wrenched his left foot severely. When seen the following morning there was a swelling over the external malleolus, extending somewhat over the anterior surface of the tibio-tarsal articulation. The same region was the seat of a faint ecchymosis, but there was no discoloration of the outer border of the foot below the malleolus, as is ordinarily the case in fracture of this process. There was no tenderness on pressure, except on the anterior edge of the malleolus and at the tibio-fibular joint. Adduction of the foot was the only movement which caused any pain. The writer at first supposed that there was a sprain at this articulation, and ordered massage for its relief, but finding that the patient was still unable to bear his weight on the injured foot, he proceeded to make a more careful examination. This showed him that there was a fracture of the malleolus, a small fragment being torn off from the surface of this process by the action of the inferior tibio-fibular ligament put violently on the stretch. The sliver of bone torn away was from the anterior border of the malleolus. Two other exactly similar cases afterward came under his observation. The sole treatment consisted in the application of moist compresses and in rest.

Rupture of the Bladder.—Dr. A. Pousson, of Paris, has written a paper on the pathogeny of two little-known varieties of rupture of the bladder, and on the means of preventing such forms of this lesion. An endeavor is made to prove that, in addition to cases of traumatic rupture and cases of spontaneous rupture—the walls of the bladder in this latter class being invariably diseased—there are, firstly, instances in which the healthy viscus distended by urine bursts under the influence of contractions of the abdominal wall during some violent voluntary or involuntary movement; and, secondly, cases in which the bladder, having undergone a morbid change, increasing rather than diminishing the resistance of its walls, may rupture through its own contractions. A bladder with hypertrophied walls may, it is argued, be ruptured by the action of its intrinsic muscles in retention through urethral stricture, and also through vigorous and irregular spasmodic contraction of these muscles, excited by the contact of fluid injected, even in small quantity, into the vesical cavity. Four recent cases are reported by the author, in which the hypertrophied and irritable bladder was ruptured during the injection of fluid, as a preliminary, in three of the instances, to lithotomy, and, in the fourth, to simple cystotomy. Dr. Pousson proposes the following classification of ruptures of the bladder, which will, he thinks, include every possible form, and remove all uncertainty on the etiological interpretation of any given case. He would divide these injuries into ruptures of the healthy bladder, and those of the diseased bladder (pathological ruptures). Under the former are included traumatic ruptures by direct and by indirect causes, and ruptures by effort. The latter, or pathological class, include ruptures by perforation, and ruptures by muscular contraction of the vesical walls. The following practical teaching is derived by the author from these considerations. In the majority of cases of rupture of the bladder by the contraction of the abdominal muscles, the injury is produced during the administration of an anæsthetic. It is advisable, therefore, before giving chloroform or ether to empty the bladder. In most instances hitherto recorded of this kind of vesical rupture, the patient was suffering from very tight stricture of the urethra. In such cases it will be advisable to remove the urine by puncture. It is held that in future a prudent surgeon, before giving an anæsthetic to any patient on whom it is proposed to perform, for example,

external urethrotomy for organic stricture or rupture of the urethra, ought always (if the bladder be much distended) to perform hypogastric puncture in order to avoid any risk of rupture of this viscus by contraction of the abdominal muscles. The demonstration of the possibility of rupture of the bladder by the action of its intrinsic muscles indicates the dangers of practising forcible injections for the purpose of re-establishing the capacity and tolerance of small and irritable bladders. It is especially in cases requiring lithotrity and suprapubic lithotomy that vesical hypertrophy and irritability are most liable to be met with. The administration of chloroform in large doses is the sole means, Dr. Poussin states, of abolishing the contractions of a bladder, whether healthy or diseased, excited by the injection of fluid.—*Revue de Chirurgie.*

Compound Fracture of the Patella, with Wound of the Knee joint.—The following case, occurring in the service of Mr. Mayo Robson, at the Leeds Infirmary, is reported in *The Lancet* of May 8, 1886: J. P——, aged thirty-five, a coachman, was kicked by a horse on the right knee on December 2, 1885, and admitted two hours afterward, when there was found to be a wound of one and a half inch over the front of the right patella, which was the seat of a starred fracture; a probe passed freely into the knee-joint. It was syringed well with perchloride solution (1 in 2,000) and dressed antiseptically, no drainage-tube being employed; the limb was fixed on a back-splint. Temperature normal throughout. Dressed for the first time on December 12th, ten days after the accident, when the wound was healed. Made an out-patient December 29th, plaster-of-Paris having been applied from the calf to the middle of the thigh, this being left on, to steady the limb, for three weeks. In March, 1886, he was quite well and able to perform his duties perfectly, the injured knee-joint moving as freely as the uninjured one.

A Bloodless Birth.—Under this title, Dr. G. W. Crider reports, in the *Cincinnati Lancet and Clinic* of May 15, 1886, the case of a woman, nineteen years of age, pregnant with her second child. The bag of waters broke early in the day, but labor did not come on for some time after. It then proceeded regularly, but after the expulsion of the child no hemorrhage appeared. The cord was only about one-third of the usual size, and was nearly bloodless. In about fifteen minutes after the birth of the child pains came on, and in about twenty minutes the placenta was expelled, with very little assistance. Judging from the stain on the linen, there was not to exceed more than a half-ounce of blood. About twenty-four hours after the birth of the child she began to have a discharge of blood, and not more than women usually have at their menstrual periods; it continued two days, then began to decrease, and in six days all discharge ceased, and she felt abundantly able to get up and go to work. The child was living and healthy.

Progressive Muscular Atrophy Beginning with the Lower Extremities.—Charcot and Marie describe a particular form of progressive muscular atrophy, which begins by affecting the feet and legs without any change in the hands and arms until after the lapse of some years. In this special form there is a relative integrity of the muscles of the root of the limbs, or at least they retain their normal condition longer than those of the extremities. The muscles of the trunk, shoulders, and face remain intact. In the muscles becoming atrophic there are fibrillary contractions, and there are vasomotor troubles in the segments of the limbs affected. There are no noteworthy tendinous contractions of the joints whose muscles are atrophied. The sensibility is usually unaltered, but cramps are frequent. There is reaction of degeneration in the atrophic muscles. The affection commonly begins in youth, often among brothers and sisters, and is sometimes hereditary.—*Revue de Médecine*, No. 2, 1886.

Puerperal Fever and Antisepsis.—M. Herrgott, of Nancy, in a communication to the Paris Academy of Medicine, mentions the cases of two women who had been confined in the same ward. In spite of the employment of the most rigorous antiseptic measures, one, who was greatly depressed physically and morally, was attacked by puerperal fever and succumbed in three days; while the other, who had a very severe labor, entirely escaped the infection. From these facts he deduces the suggestion that, however valuable and true the doctrine of microbes may be in the generality of cases, it is not capable of explaining all the facts of infection. "Too absolute, too general rules lead observers to neglect an essential element in diseases—the patient."—*The Lancet*, May 8, 1886.

Topical Applications of Bacterium Termo in Lupus.—Dr. J.V. Bellaserra writes in the *Revista de Ciencias Médicas* of May 10, 1886, that he has made some essays in bacteriotherapy for the cure of lupus vulgaris. He first made a number of linear scarifications over the diseased surface, and then applied a layer of absorbent cotton dipped in broth containing a pure culture of bacterium termo. This was covered with a piece of gutta-percha tissue, the whole being held in place by adhesive plaster. The application was renewed every twenty-four hours, the scarifications being made, however, only every second day. The patient was still under treatment, and the experiment had not been continued long enough to obtain any definite results.

Tender Points in Chorea.—Marie draws attention to the fact that in the true chorea of Sydenham tender points have been described over the spine, the thorax, and the abdomen. In addition to these, however, he has noted a number of cases in which there was tenderness over the ovary also, and that this is present on the same side as that on which choreic movements first appeared.—*Edinburgh Medical Journal*, April, 1886.

Fracture of the Coracoid Process of the Scapula.—Dr. L. E. Borcheim reports the following case in the *Atlanta Medical and Surgical Journal* for May, 1886: A man, aged sixty-six, while walking the street was struck full on the right shoulder by a runaway horse, being lifted bodily and violently thrown against an iron column. He complained of severe pain and said his arm was broken. Manipulation about the coracoid process was exquisitely painful, and some crepitation was made out, but there was very little displacement, owing to the strong ligamentous fibres which are inserted into, and distributed over, this process. The treatment consisted in relaxing the pectoralis minor, coraco-brachialis, and biceps, which was accomplished by placing the arm in a large triangular sling, flexing the forearm on the arm, and keeping it close to the chest by a turn of a roller bandage.

Salol.—This is a new preparation, possessing antipyretic and antiseptic properties, discovered recently by Professor von Nencki. It is a combination of salicylic acid and carbolic acid, a salicylate of phenol. It is a white powder, rather greasy to the touch, of a faint, aromatic odor, and almost tasteless on account of its insolubility in water. It is, however, soluble in alcohol. Professor von Nencki has experimented on animals with salol, and finds that the entire quantity is excreted in the urine under the form of urate of salicyl and sulphophenol, there being thus a simple decomposition of the salt in the organism without any modification of its constituents. It was found that it was the pancreatic fluid which effected this decomposition, as the salol was immediately broken up into its constituent parts when mixed with chopped-up pancreas. This fact of decomposition occurring in the duodenum rather than in the stomach would account for the absence of nausea and other disagreeable gastric symptoms. This experimenter

also found that a dose of one drachm *per diem* was well borne by man. At a meeting of the Medico-pharmaceutical Society of Berne (*La Semaine Médicale*, April 14, 1886), M. Sahli related his experience with the new drug, and said that he had taken as much as two drachms in a day without experiencing any disagreeable effects, although some of his patients had noticed a very slight ringing in the ears after large doses. He was in the habit of giving it in doses of one and a half to two drachms in the course of the twenty four hours, and never had any serious complaint from his patients. It colors the urine almost black, just as carbolic acid does—indeed, it contains no less than thirty-eight per cent. of carbolic acid. M. Sahli had tried salol in all forms of rheumatism, and had always found it to act at least as well as salicylic acid, and he thought the fever was reduced even more rapidly, possibly by reason of the phenol which it contained in such large proportion. One case of chronic urticaria which had resisted every kind of treatment was quickly relieved by salol, as were also several cases of obstinate suborbital neuralgia. This drug is also, the speaker asserted, a powerful antipyretic. It is given for this purpose in the same doses as for rheumatism—thirty grains three or four times a day. In one case of phthisis he saw a sudden fall of 7°, from 103.5° to 96.5° F., with no unpleasant symptoms following, after a single dose of thirty grains; he does not, however, advise the unrestricted use of salol, or of any other antipyretic, in phthisis. The antiseptic properties of salol are well marked, and it possesses the advantage, with iodoform, of not being soluble in water, and hence of not being readily washed away with the secretions. The speaker had used it with good results in ozæna and otorrhœa, and thinks that the powder suspended in water might be used with advantage as an injection in gonorrhœa. By reason of its antiseptic properties, also, it is indicated in intestinal catarrhs, in typhoid fever, cholera, etc., and the speaker thought it might be given with advantage in diabetes, in which both salicylic acid and phenic acid were often prescribed. He urged his hearers to make trial of salol, and assured them that the results obtained would prove most satisfactory. It possessed the great advantage over salicylic acid in being tasteless, and in not causing nausea or other unpleasant effects. Other speakers at this meeting confirmed the statements of M. Sahli concerning the value of salol, and all united in recommending more extensive trials of the drug in rheumatism, fevers, and septic diseases. It was spoken of very highly also as a dentifrice in order to prevent caries of the teeth.

Four Methods in which Articular Cartilage may be Destroyed.—At a recent meeting of the Medical Society of Victoria (*Australian Medical Journal*, March 15, 1886) Professor Allen presented a series of specimens illustrating some of the modes in which the cartilage may be destroyed in disease of the articulations. 1. The head of the femur from a case of osteitis. The nutritive relations between the articular lamella of bone and the cartilage were arrested, and the latter was separating in large flakes. In the acetabulum the cartilage had disappeared, the bony floor of the cavity was necrosed throughout its entire thickness, and was breaking up into fragments. There was extensive suppuration in and around the joint, but the pus had not yet made its way into the obturator internus, the periosteum over the pelvic surface of the floor of the acetabulum not being perforated. Such a process of stripping of cartilage almost *en masse* is rarely seen. 2. The medio-tarsal joints denuded of cartilage by intra-articular suppuration, originating apparently in suppurative periosteitis of the calcaneum and cuboid. In this form the cartilage first becomes swollen, soft, and succulent, and of an opaque grayish color; then the surface becomes filamentous by the unequal process of softening, and gradually the whole thickness of the cartilage, or of portions of it, may be removed, the changes in the subjacent bone being relatively insignificant. 3. The much slower process seen in many cases of chronic synovitis was exemplified by specimens of protracted disease of the knee and ankle. Here the synovial membrane becomes hyperæmic and swollen, densely infiltrated with leucocytes, and at last is practically composed of granulation tissue which may or may not secrete pus. The more rapid the disease and the greater the hyperæmia, the more abundant will suppuration be; but in chronic cases, with scarcely any hyperæmia and a minimum of swelling, fringes of moderately vascular granulation tissue may form without suppuration. It is in these very chronic cases that the changes in the cartilage are best seen. In the ankle exhibited, little, gray, fleshy processes were slowly growing from the edge of the synovial membrane over the cartilage, which itself was as yet little altered. But with the continued growth of these highly cellular processes the cartilage beneath becomes eroded, literally eaten away, the destructive action being patchy or general, according to the distribution of the cellular ingrowths from the synovial membrane. In relatively acute cases the process is modified by the free formation of pus, and in very acute cases there is no time for the development of the cellular ingrowths. 4. This variety of destructive change in the cartilages was illustrated by various joints of the tarsus from a case of chronic osteitis. The cartilages become pale pink, either uniformly or in patches, and are gradually replaced by granulation tissue growing slowly from the medullary substance in the Haversian canals of the subjacent bone. As the process of replacement progresses, the surface of the cartilage becomes more distinctly vascular and soft, so that the finger-nail readily indents it, and the granulation tissue may even form slightly elevated ruddy patches in the midst of the pinkish less altered cartilage around. These four varieties of destructive change in cartilage are comparatively seldom seen in pure forms in the post mortem room; in cases which run to amputation or to a fatal issue acute inflammations have often alternated with the more chronic processes, and synovial, periosteal, and endosteal lesions have accumulated themselves upon one another. The speaker exhibited a foot, as an instance in point, in which the medio-tarsal joint was utterly disorganized by suppuration; the periosteum around the os calcis was thickened and softened, readily peeling from the subjacent bone, and at parts separated from it by abundant pus; the ankle showed the slow growth of cellular processes over the cartilage, apart from suppuration, while the anterior tarsal and tarso-metatarsal joints exemplified in different degrees the development of granulation tissue from beneath the cartilages. The processes thus described are quite distinct from the gradual erosion of cartilage which occurs apart from inflammation, especially in advanced age; and they are also distinct from the changes included under the title of chronic rheumatoid arthritis. It must be remembered, however, that the eburnation of the articular surfaces and the growth of osteophytes, so characteristic of rheumatoid arthritis, may be variously complicated by the various inflammatory processes described above, and, if the early stages of eburnation could be observed, it is probable that the slow development of a granulation tissue from the subjacent bone, and its slow conversion *pari passu* into ivory bone, would be the true pathological change, modified by imperfect ossification of the granulation tissue on the one hand, and by intercurrent attacks of synovitis on the other. The close anatomical relations between cartilage, synovial membrane, periosteum, and medullary osseous tissue are now well understood; the gradual transition of articular cartilages at their edges into the connective tissue of the synovial membranes suffices to explain some of the differences which are so often seen between the lesions at the margins and those toward the centres of articular surfaces, while the varying degree of coaptation, pressure, and attrition of the articular surfaces may explain other differences.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

LITERARY RECREATION FOR MEDICAL MEN.

THE recent publication in England, by men of note, of lists of the best hundred books for general reading, has excited general interest. This interest has been shared by all who have any acquaintance whatever with literary matters. Certainly, all possessors of or aspirants for literary taste must look upon this publication with commendation. In these days a purely literary publication from the pen of a medical man is no rarity. The subject, therefore, intimately concerns our own profession. As might be expected, the variety of books named in the published lists is very great. The latter have all been compiled by men of a distinctively literary reputation. On these topics as well as on all others, a man's judgment is largely determined by his occupation. A physician has very little time in his student days to dwell upon mere literary style. He is after facts. The wide extent of ground which must be covered, as a matter of routine, is so great that he is effectually debarred from systematic outside reading.

Unless a taste for literature is acquired before commencing medical study, the chances are that it will never furnish a means of enjoyment in leisure moments. These are few and far between. With most men the struggle for a competence, with its attendant mental and physical exhaustion, forbids much literary recreation. When in later years a competence is assured, and some of the more onerous professional duties can be laid aside, the chances are that the long slumber of literary taste will not be shaken off.

Those physicians who suffer least from this form of mental inactivity are those whose taste or occupation lead them to contribute to their own professional literature. At the present time, writers in any professional field have a critical audience to please. It may be disputed whether or not the ranks of the medical profession contain relatively more literary men than they did fifty years ago. But they do contain more men relatively who can appreciate a true literary style. Particularly is this the case in regard to the terseness of any article. He alone receives consideration and makes a lasting impression who clothes his ideas in brief, yet vigorous language. The reading of long articles is left to the few. Prosiness and prolixity in writing on professional topics have received their death-blow. Brevity is the soul of influence as well as of wit.

One thing is noticeable in those whose occupation may not be a literary one, but who yet find recreation in literature. It is that this recreation comes more from the thorough perusal of one author than from the desultory perusal of many. A well-thumbed Shakespeare may speak far more eloquently of its possessor's literary activity than shelves of rich editions. As we con the pages of the older novelists and dramatists, we perceive a most wonderful insight into the relations between mind and matter. Perhaps writers in these latter days have never equalled their predecessors in this respect. Who does not find in Shakespeare that faculty of insight which may find its highest expression in solving the mysteries of obscure bodily disease? Or who cannot see portrayed in some of Dickens' doctors the foibles, somewhat exaggerated perhaps, of his professional neighbor? If he be frank enough he may see reflected some of his own.

The physician is the last for whom a list of best books may be made out. The scientific aspect of medical work is now many-sided. The paths it suggests lead off in many directions. Each one can be followed with both pleasure and profit. But even these are hardly recreation enough for the physician. That comes only when he can step out of his professional environment. For the time being he must cease to be a physician.

There can be literary work and there can be literary recreation. The two are distinct. Consideration of medical questions of scientific import necessitates the former. The latter comes from outside the domain of professional work. In the former one deals entirely with hard facts. Reason is the motive power, the working force. In the latter, imagination, "the world's sweet inn from care and wearisome toil," comes into play. It conduces to a well-rounded mental growth. Then literary work proper is resumed with renewed zeal. We are borne along with the zeal coming from the power of new ideas, our mental processes are more vigorous and more logical. We feel that our recreation has benefited us. We realize that "the best man is he who most tries to perfect himself, and the happiest man is he who most feels that he is perfecting himself."

THE FURTHER EMPLOYMENT OF BACTERIO-THERAPY.

WE have already called attention to the novel method of treating pulmonary tuberculosis proposed by Professor Cantani, of Naples, viz., the inhalation of fluids containing the *bacterium termo*. Further trials of this have been made by Dr. Brehmer at his hospital at Görbersdorf (*Allgemeine Med. Centr.-Zeitung*, 1886, No. 28), and recently again by Dr. Laaser, of Breslau (Ibid., No. 34). Dr. Laaser states that among seven patients whom he treated by the new method two were improved and one was cured. The first case in which there was improvement was that of a young peasant woman, who was treated also by lavage and antipyrin. Some of the improvement was ascribed to these latter measures. The second patient was in the third stage of phthisis and bedridden. After the inhalations she was able to get up and go about, her temperature fell, and her bodily strength increased. She then had an attack of localized pleurisy, and as the inhalations caused vomiting they were discon-

tinued. The third and "cured" case was that of a young laborer, who, when admitted to the hospital, was found to have a large cavity in the right lung. His evening temperature was 39.5° C., and the expectoration was copious and fetid. Inhalations of turpentine and carbolic acid lessened the odor, but did not relieve the fever, and the patient's strength continued to fail. Tubercle bacilli being found in the sputa, he was placed upon daily bacterial inhalations. The odor of the sputa soon disappeared, as also did the bacilli, the patient's condition steadily improved, and in four weeks he was discharged cured!

THE PROPHYLACTIC VALUE OF CHOLERA INOCULATION.

We referred in these columns, under date of October 3, 1885, to the statistics of Ferrán's preventive inoculation during the cholera epidemic in Spain last summer. The figures there given were of the results of cholerization, as the author of the method terms it, in seven small towns only. We have just received a pamphlet embracing the statistics of twenty-one additional places. The reports are for the most part prepared in the same careful manner as were the others, being written by the local physicians, and certified to as correct by the alcalde and other municipal officers and the parish priest, the statements being furthermore sworn to before a notary. We must, therefore, accept the figures as correct, and free from any suspicion of fraud or of having been twisted to bolster up Ferrán.

Four of the towns were not visited by the cholera at all, and of these we shall speak later. In two others the statistics are not complete, the compilers having omitted to give the population in one instance, and the number of individuals inoculated in the other. There remain fifteen communities concerning which the information given is satisfactory, and from which we can draw some conclusions as to the utility of the method. The total population of these fifteen towns amounts to 92,510, of which number 8,238 were inoculated by Ferrán or his assistants, leaving 84,272 unprotected by cholerization. Of the non-inoculated 6,014 (or 7.13 per cent.) were attacked by the disease, and of this number 2,467 (or 41.02 per cent.) died. Of the inoculated 123 (or 1.49 per cent.) were attacked, and of these but 25 (or 20.33 per cent.) died. Putting together the two sets of statistics collected from twenty-two towns, with an aggregate population of 134,151, we find that of the non-inoculated 7.199 per cent. were attacked by the cholera, while of the inoculated only 1.204 per cent. suffered. The mortality of the disease was, of the non-inoculated 43.31 per cent., and of the inoculated 28.17 per cent. of those attacked.

Several instances of apparent protection by inoculation are mentioned which are rather striking, though not necessarily conclusive. In Adzaneta the family of the municipal secretary, Sr. Plá y Plá, was composed of five individuals, four of whom submitted to cholerization. These four passed through the epidemic without suffering from any symptoms of the disease, while the one who was not inoculated was stricken down by cholera and died. In Alcalá de Chisvert there were four physicians at the outbreak of the pest, and naturally they were exposed to constant danger in the discharge of their duties. Three of these, who had been inoculated, passed safely through the epidemic, while the fourth, who had not been inoculated, died. In four families in the same town one member of each, and that the only one not inoculated, died of cholera, while the others, who had submitted to the operation, escaped. Several precisely similar cases are related as occurring in other places.

It has been said by many that the inoculation by means of the virus prepared by Ferrán, if it had any effect at all, would expose those operated upon to even greater danger. But this assertion would seem to be disproved by the facts presented in these reports. There were four towns in which no cholera appeared during the summer, although, in anticipation of an attack, inoculations to the number of 5,504 were made. If the inoculation were likely to cause cholera in the individual operated upon, it would hardly be possible for so great a number to escape. From one of these towns, La Roda, seventeen individuals went into an infected district. Nine of these had been inoculated, and eight had not. None of the nine suffered during their exposure, but six of the eight non-inoculated persons were seized with cholera and two died.

In most of the reports it is stated that no symptoms other than those commonly following inoculation were caused by the operation, and in only four cases out of the many thousands did abscesses at the point of insertion of the virus occur. It would thus seem to be proven by these statistics that the inoculations are harmless, or at least no more dangerous than hypodermic injections of some inert fluid. And in view of this fact, the results are such as to offer encouragement for further trials. The cable reports that the Spanish Government has granted permission to Ferrán to continue his inoculations this summer, should apparent necessity for them arise, and we may therefore expect even more extensive experiments to be made, if cholera revisits the country. We sincerely hope the scourge will not return, but should it do so, we shall be interested in studying the results obtained by the method, and shall hope to present them in due time to our readers.

THE NEW YORK PHYSICIANS' MUTUAL AID ASSOCIATION.

We have just received the Seventeenth Annual Report of the Physicians' Mutual Aid Association, whose benefits and work we have heretofore often commended to the profession of New York City and Brooklyn. We invite especial attention to the fact that the Trustees have completed arrangements for extending its operation to the entire State, which cannot fail to largely increase its usefulness. Any member of the regular profession under fifty years of age and in good health is eligible to membership. Its life-insurance feature is valuable, but no less so is the benevolent part of the work, whereby a sick member, or the family of a deceased member, may be assisted from the interest of the permanent fund, which has now increased to nearly $14,000. The latest donation to this fund was from Mrs. Austin Flint, amounting to $450. The cost of becoming a member is $3, including the first assessment, and we believe the present

management will not be disappointed in hoping for the co-operation of the entire medical fraternity of the State. Its past history furnishes every guarantee of successful administration in the future.

Application for membership may be made to the Secretary, Dr. W. Y. Alexander, Station M, New York City, or to any of the following gentlemen who have already been appointed Medical Examiners: Dr. F. H. Potter, of Buffalo; Dr. H. Flood, Elmira; Dr. S. Ely, Newburg; Dr. W. S. Ely, Rochester; Dr. W. W. Hewlett, Babylon; Dr. C. M. Wilson, Gouverneur; and Dr. W. E. Ford, of Utica.

THE DELICACY OF THE SENSE OF SMELL.

The sense of smell is probably the leading sensorial endowment in most insects, and it does for them what sight and hearing do for man. Its potency in helping along intelligence is very great, since we know that, mentally, insects stand at the head of the invertebrate, as man stands at the head of the vertebrate, world. The sense of smell is probably acute in some fishes, as, for example, the shark; this is the most active, if not the most intelligent, of fishes, and it has an olfactory mucous membrane which, if spread out, would cover some twelve square feet. The sense falls in value in the amphibia, reptiles, and birds, but rises again in the mammalia, though not in proportion to intelligence. Its extreme acuteness in the dog, the most intelligent of animals short of quadrumana, is well known. In man the sense of smell is subordinate, and even rudimentary. Olfaction adds to man's enjoyment, preserves him from some dangers, but does not very much extend his knowledge of his environment.

Yet, despite the comparative insignificance of this sense in man, its delicacy is most marvellous, and by it we can appreciate more minute subdivisions of matter or the impact of more infinitesimal molecular vibrations than by any other of the avenues to the brain.

Professor Valentin has made some interesting and striking experiments in proof of this. He found that a current of air containing $\frac{1}{300000}$ milligramme of bromine, or $\frac{1}{500000}$ milligramme of sulphuretted hydrogen, or $\frac{1}{2000000}$ milligramme of oil of roses, could be perceived by the sense of smell. He also determined that the amount of odoriferous air which must pass over the olfactory membrane in order to excite the sense of smell was from fifty to one hundred cubic centimetres (one-tenth to one-fifth of a pint). He calculated, therefore, that the actual amount of bromine necessary to excite a sense of smell was $\frac{1}{6000}$ milligramme, of sulphuretted hydrogen $\frac{1}{10000}$ milligramme, of oil of roses $\frac{1}{40000}$ milligramme (about $\frac{1}{12000}$ of a grain).

Two recent experimenters, E. Fischer and F. Pentzoldt, of Erlangen, have found two other substances which far exceed the foregoing in their capacity for affecting the olfactory nerves. These were mercaptan (sulphuretted alcohol) and chlorphenol. They found that in air containing $\frac{1}{2500000000}$ milligramme to the cubic centimetre of chlorphenol, and $\frac{1}{2500000000000}$ milligramme of mercaptan, these substances could be appreciated, and it was estimated that only $\frac{1}{48000000}$ milligramme of chlorphenol, and $\frac{1}{480000000000}$ milligramme of mercaptan, is necessary to excite a sensation of smell. There exists, therefore, a substance which is so small a subdivision as $\frac{1}{2760000000000}$ grain, or not quite one-three-billionth of a grain is capable of calling out a nerve impulse. This subdivision of matter is quite beyond comprehension, yet the nose alone can appreciate it. The smallest subdivision appreciable by the eye through the spectroscope is $\frac{1}{140000}$ milligramme of sodium, which is a two hundred and fifty times coarser division of matter than the minimum of odor-exciting mercaptan.

On account of the extraordinary power of mercaptan it is proposed to put it to some practical use in testing currents of air, ventilation, etc.

THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

We have already alluded to the plan started in practical form, by a Southern physician, of creating a Congress of American Physicians and Surgeons.

This is to be composed of the nine national associations already in existence, viz.: The Surgical, Ophthalmological, Otological, Neurological, Laryngological, Gynecological, Dermatological, Climatological, Clinical, and Pathological. The plan provides that these societies shall meet in Washington at the same time, elect a president, and have some common sessions with addresses. Each society is to preserve its own name, constitution, and by-laws, hold separate meetings, and in every way preserve its own autonomy.

The advantages of such a meeting and mingling of different societies are at once apparent. Many physicians hold membership in two of the national associations, and to them it would be a convenience. Many would feel an interest and receive benefit from attending other meetings and coming in contact with professional brethren having a different special but a common general aim.

Aside from this, a congress of the nine different special associations would bring together a body of men which would do honor to American medicine. Most, if not all, of these societies have special requirements for membership, and it is quite safe to say that they include the best men, East, West, and South, in all the different departments of medicine.

The congress will not be entirely a meeting of specialists, since such associations as the Clinical, the Surgical, and the Climatological may include general practitioners.

But, despite the attractiveness of the idea of a congress, there are some drawbacks, and it will require a great deal of assiduous work to bring it into actual existence.

Some of the associations do not care to meet in Washington, which is not a medical centre, and where a congress of postmasters would receive much more social and official attention than one of medical men—each of whom controls but a single vote.

The question of finding a time and place agreeable to all is a serious one. Yet it should not prove insuperable, and some of our associations might concede a little for a common good.

TUBERCULOSIS IN CHILDREN AND THE QUESTION OF CONGENITAL TUBERCULOSIS.

It is generally asserted that chronic tuberculosis is a disease which is rare in early years but progressively increases in frequency. M. Jules Simon, in his "Conferences Therapeutiques et Cliniques sur les Maladies des Enfants," states that tuberculosis is rare in the first year of life; from the age of one to three it affects by preference the abdominal cavity, while from the age of three to ten one finds it oftenest in the cranial cavity; after the latter age pulmonary tuberculosis predominates, increasing in frequency with years, and attaining its maximum between the ages of twenty and thirty, or, as more recent writers have it, increasing in relative frequency even up to the later years of life.

With regard to tuberculosis in infants, and especially the question of congenital tuberculosis, Dr. W. Schwer, of Kiel, has recently (*Allgemeine Med. Central-Zeitung*, 1886, No. 6) contributed some interesting facts. Schwer's work is an inaugural dissertation, and is based on a study of the autopsies made upon infants at the pathological institute of the Kiel University. His statistics include 123 autopsies on tuberculous children made between the years 1879 and 1883, and are a continuation of Simmonds' statistics which covered the years 1873–1879. The following table shows the ages at which tuberculosis began to be observed:

Age.	[illegible]	[illegible]	[illegible]
Still-born	[illegible]	[illegible]	[illegible]
Under four weeks	[illegible]	[illegible]	[illegible]
Between 5 and 9 weeks	[illegible]	[illegible]	[illegible]
Between 3 and 5 months	[illegible]	[illegible]	[illegible]

Basing his opinion on the fact that no tuberculosis was found post-mortem in children under nine weeks of age, Dr. Schwer concludes that tuberculosis is never a congenital or connate disease.

The table continued is as follows:

Age.	[illegible]	[illegible]	[illegible]
6 to 12 months	[illegible]	[illegible]	[illegible]
2 years	[illegible]	[illegible]	[illegible]
3 years	[illegible]	[illegible]	[illegible]
4 years	[illegible]	[illegible]	[illegible]
5 years	[illegible]	[illegible]	[illegible]
6 to 10 years	[illegible]	[illegible]	[illegible]
11 to 15 years	[illegible]	[illegible]	[illegible]

From these figures the author concludes that tuberculosis is very prevalent in the first years of life and then gradually diminishes up to the time of puberty. Against this there will be very little dissent, but Dr. Schwer's view that tuberculosis is never congenital is not borne out either by his own statistics or those of others. It is only probable, and not certain, that the infants who died of tuberculosis at the age of nine weeks were not born with the disease. However this may be, a year ago Johne (*Fortschritte der Medicin*) reported a case of undoubted fœtal tuberculosis, and Dr. Haupt, of Soden, affirms that veterinarians have often observed fœtal tuberculosis in animals.

As to the distribution of the tuberculosis in children, Schwer analyzes 123 cases. In these there was observed tuberculosis of the liver, 104 times; lungs, 103 times; intestines, 63 times; meninges, 53 times; thyroid, 12 times; striped muscles, twice.

We cannot but think that tuberculosis exists more frequently among the children of the lower classes of Europe than among those of America. On this point, however, there are unfortunately no very trustworthy statistics, so far as we are aware.

The report of the New York City Board of Health, for the year 1875, gives the following:

[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]

This makes a mortality of 761 from tubercular disease in a total mortality under the age of one year of 8,540, which gives a per cent. of about eight. Schwer's per cent. of tuberculosis among 160 children dying between the age of six and twelve months was 17.5.

MAD KINGS.

The late King Louis II., of Bavaria, was of a mad family. If accounts are correct, his father was of unsound mind, and his brother is known to be an imbecile.

Dr. Ball, in his "Leçons sur les Maladies Mentales," describes a form of insanity that very well fits the case of King Louis. There is, he says, a kind of maniacal excitation and disordered action of all the faculties, without any clear derangement of intelligence. Ideas are quickly flowing and exaggerated, but there is no incoherence. The patients often show a remarkable development of certain intellectual powers, especially in poetic or artistic directions. Their minds are filled with speculations and new projects, and the moral sense is greatly weakened or perverted. Dr. Ireland finds another royal illustration of this psychosis in Mohammed Toghlak, Sultan of India, in the fourteenth century; and, as we will show later, it has plainly affected one of the czars of Russia, and very likely members of other royal families.

The German writers have given to this form of insanity the name of paranoia, and this was the diagnosis made by the late king's physicians.

In earlier times there were many royal families in whom mental disease and decay showed itself. Indeed, there is scarcely a family, whose members ruled despotically for many years, in which some taint did not develop. The gradual extinction of many of these families, through the degenerative taints which have developed, has been well shown by Dr. Jacoby and Dr. Ireland. Uncontrolled exercise of power, the free opportunity for the indulgence of every appetite and caprice, seem surely to bring on disease either in the individual himself or his descendants. In modern times monarchs have to regulate their conduct and restrain their passions more than formerly, and in consequence royalty is a much more healthful occupation than it used to be.

In the Claudian-Julian family, beginning with Julius Cæsar himself and ending with Nero, we have an almost unbroken line of neuroses. Cæsar himself was epileptic, but probably the disease developed late in life, from exposure and excesses, and did not much affect his health.

Augustus, his grand-nephew, had, it is believed, writer's cramp; Julia, his daughter, seems to have been little better than a nymphomaniac. She had an imbecile son. Tiberius was a man naturally heartless, cruel, and licentious. In his later years he seems to have lost all moral sense, and illustrated the most shameless sensuality and cruelty. Caligula, reputed great-grandson of Augustus, was epileptic as a boy, badly formed and weak-minded as a man. He stuttered, was insomnic, and apparently had hallucinations. Claudius was also weak-minded, timid, and credulous, with unsteady gait, weak knees, shaking head, and dribbling lips.

In Russia, the present House of Romanoff has shown plain evidence of the development of mental weakness and defects. The sister of Peter the Great was a brilliant woman, but his two brothers were weak-minded and had physical defects. Peter himself, though a man of genius, bore traces of the family neurosis. He had, at times, convulsions, and was, when young, the victim of a morbid antipathy to the water. Peter's daughter, Elizabeth, was a dissolute and hard-drinking woman. His grandson was weak-minded, coarse, and extremely licentious. The Emperor Paul, who succeeded Catherine II., was, according to Dr. Ireland, unquestionably deranged. His whims and fits of unreason were much more coarse and brutal in their tendency than those of King Louis, but they suggest the same malady implanted on a man of less refined nature and duller sensibilities. Paul was treated finally in much the same way as King Louis, only, as the former refused to abdicate, he was summarily strangled. The House of Romanoff has improved in the last three generations, as the result, doubtless, of the constant infusion of Teutonic blood.

A study of the royal families of France and of England would bring to light some interesting neuroses, but we have said enough to illustrate our subject.

THE DEATH OF PROFESSOR GUDDEN.

After all, the saddest thing in connection with the late King of Bavaria was the death of his physician, Professor Gudden. The last mad act of a selfish and useless life was to end the career of this distinguished and useful man. King Louis will be given a place in history because he was by chance a king. Professor Gudden's name will live because he contributed to science a new method of research, which has made an epoch in our knowledge of the structure of the body. The "atrophy-method" of Gudden is one now familiar to all students of medicine; it has helped immensely in elucidating the difficult problems of brain anatomy.

Professor Gudden died in the discharge of his duty, while struggling to prevent a madman from committing suicide. To his scientific honors he has added the crown of martyrdom; and so, with all the more care should his name be remembered and his memory cherished.

One Dr. Villavicencio [illegible] to go to New Orleans and start an institute for inoculating against yellow fever. To this the Louisiana State Board of Health object, and announce that if Dr. Villavicencio land with his microbes he will be disinfected and sent back.

News of the Week.

The Statue of Hunter.—On the 29th ult. a statue of John Hunter, "the father of scientific surgery," was unveiled in the new Museum at Oxford by Her Royal Highness Princess Christiar, in the presence of a large assemby of spectators. The statue is one of five statues, representing heroes of science, presented to the university by Her Majesty the Queen. It represents the great *savant*, with a remarkably keen and searching countenance, standing with the legs crossed and supporting himself on a pillar or post.

Auscultation of the Eyeball.—M. Gené has recently described to the Biological Society of Paris a new method of estimating the tension of the eyeball. This consists in auscultating the organ by means of M. d'Arsonval's telephone. The instrument is applied to the globe, and a sound, such as that of the interrupter of a faradisation instrument, made to pass; the differences of degree and intensity of the sound as perceived by the observer afford a valuable and accurate means of diagnosis. M. Gené's experiments being as yet somewhat incomplete, he hopes at some future time to lay the subject before the Society in greater detail.

Preventive Inoculation in Yellow Fever—A French Commission Appointed.—The subject of inoculation for yellow fever, as practised by Dr. Domingos Freire, of Rio de Janeiro, was brought under the notice of the Société de Biologie of Paris at a recent meeting. M. Rebourgeon communicated the results obtained by himself and Dr. Freire in December, 1885, and January and February, 1886. The weather during these months in Brazil was intensely hot, and yellow fever prevailed severely. Of 3,051 subjects inoculated at Rio, not one had died, whereas in the same districts and houses 278 non-vaccinated had succumbed to the disease. M. Rebourgeon said that the number of the inoculated had now reached 6,000, and not one of them had been attacked with the fever; and, what was more remarkable severe cases inoculated in the second stage of the disease had all recovered. In reply to M. Brown-Séquard, M Rebourgeon said that but few foreigners were inoculated, but yellow fever is at the present time creating great ravages among the Brazilians and mulattoes; the negroes even are being largely attacked, which is a rare occurrence, and the area of the disease was extending inland from the littoral. He explained that some specimens of virus sent two years ago to M. Cornil, and found by him to be worthless, had not been sent by Dr. Freire, but by opponents to his method. He had often inoculated himself, and was so convinced of the efficacy of the attenuated virus that he had frequently offered to undergo inoculation with the yellow fever itself. He presented a specimen of the vaccine to the Society for examination. In reply to M. Maurel, he said that he had met with yellow fever at an altitude of more than seven hundred metres; and had seen many cases among emancipated negroes, although less than among mulattoes, who were attacked in about the same proportion as the whites. M. Maurel attributed the former immunity of negroes to their vegetable diet, but since emancipation negroes

had largely adopted the customs of the whites, and consumed more animal food. A commission to study the method of inoculation was appointed, consisting of MM. Brown-Séquard, Cornil, Duval, Bourquelot, and Maurel.

The Report of the Albumin Test Committee of the London Clinical Society was recently made. In it the committee briefly reviewed the various modes of urinary testing for albumin in common use, and compared in turn Dr. Oliver's test-papers, Dr. Johnson's picric acid method, the potassio-mercuric iodide and acid, Dr. Pavy's pellets, the acid brine method, picric acid and brine, the acetic acid, and the nitric acid methods. The portability and delicacy of reaction of Dr. Oliver's papers were strong recommendations, but, apart from the question of easy carriage and compactness, the committee considered that nitric acid was most reliable and delicate. All the methods were said, however, to be respectively useful for the determination of the various proteids that might be contained in urine.

The Treatment of Stricture by Electrolysis.—In consequence of a paper read upon this subject before the Royal Medical and Surgical Society recently, by Dr. Stevenson and Mr. B. Clark, much discussion has arisen, and a large number of English surgeons are testing it. A special department for this treatment has been made at St. Peter's Hospital for Urinary Diseases.

A New Method of Treating Thoracic Aneurism.—Under this title Dr. Richard Barwell describes a method which he has recently employed. It consists in puncturing the sac with a hollow ivory needle, and passing through this and into the sac about ten feet of fine steel wire. This latter is connected with a galvanic battery (positive pole), and a current of nine or ten milliampères is passed through it for an hour. In the case in which this method was tried a considerable degree of firm coagulation was obtained, but the aneurism had a second sac and the patient was nearly moribund before the operation. He died a week later.

The Extent of Cholera in Italy may be gathered from the following: From May 18th to June 2d there occurred in Venice 221 cases, 110 deaths; in Bari, 59 cases, 23 deaths; in Ostuni, 13 cases, 4 deaths; in Brindisi, 5 cases, 2 deaths; in Oria, 9 cases, 5 deaths. The epidemic is growing at Venice, and about twenty cases a day are reported; the general tendency of the epidemic seems to be to progress toward the Austrian frontier.

Philadelphia County Medical Society and Female Physicians.—The Philadelphia County Medical Society, at its regular monthly meeting, June 2d, balloted for twenty-five candidates for membership, and elected them all except Dr. Clara Marshall, a professor in the Women's Medical College, who failed to secure the necessary two-thirds vote. Dr. Marshall's name had been proposed several times before, and the vote has always been against her. It was decided to push the prosecution of illegal practitioners, and money was contributed for that purpose. Three bogus doctors have already been sentenced to imprisonment, and fourteen more are under indictment.

Death of Dr. Horace P. Farnham.—After a long and painful illness Dr. Horace Putnam Farnham, of this city, died on June 9th. He was born in Salem, Mass., in 1822, was graduated from Harvard University in 1843, and immediately afterward began the study of law in the office of Rufus Choate. He then went through the course of the Dana Law School of Harvard, and was admitted to the bar, but never practised. He had a fondness for medicine, and after studying for some time he entered the Jefferson Medical College, of Philadelphia, from which he was graduated in 1860. In 1861 he began to practise in this city, and has lived here ever since, always having a large and lucrative practice. Dr. Farnham was a member of many of our local medical societies.

Dr. Oliver Wendell Holmes is to receive the honorary degree of LL.D. from the University of Cambridge.

Aneurism of the Hepatic Artery.—Dr. R. Caton has reported a case of this kind to the London Clinical Society, being the eleventh case on record. The patient, a man of forty, suffered mainly from symptoms of obstructive jaundice, but he had great pain and finally vomited blood.

"The Pictures of So-called Cigarette Makers that are displayed in the windows of cigar stores in this city insult hundreds of girls who make an honest living by rolling cigarettes in the factories. They are certainly a disgrace to the men who exhibit them."—*N. Y. Sun.* "Our contemporary, the *Sun*, is making war upon the indecent photographs and lithographs so plentifully exhibited in the windows of cigar stores. Its criticisms are just and proper. These pictures are becoming more and more immodest. They are not a legitimate advertisement, for it cannot be shown that they increase the sale of cigars and cigarettes; and they offend the public sense of decency."—*N. Y. Times.* The Record was the first to call attention to the point made by the *Sun*; and so far as the Richmond firm then referred to is concerned, no criticism can now be made. They have removed the photographs first exhibited. Unfortunately they left an example.

A New Society for the Prevention and Treatment of Venereal Diseases.—The New York Society for the Prevention of Contagious Diseases has been recently incorporated, with Dr. Herman Loewenthal as President, Dr. John Alsdorf, Secretary, and John J. Bowes, Treasurer. It will establish an infirmary for the reception and gratuitous medical and surgical treatment of sufferers from these diseases, either inherited or transmitted. Incidentally the Society will oppose all measures having for their object the State regulation of vice, and by establishing sanitary surveillance without legalization do away with any excuse for such regulation. The Society's Board of Directors includes well-known physicians, lawyers, merchants, and manufacturers, among whom are Professors T. Gaillard Thomas and Alfred L. Loomis, Coroner Levy, Judge Donohue, Frederick Hollender, Vice-President Charles L. Rickerson, of the Catskill Steamboat Company; Colonel Benjamin A. Willis, and Dr. James O'Reilly, who is to be Superintendent of the proposed infirmary.

LANOLIN AN OLD REMEDY.—It appears that lanolin is not entitled to take rank among the most recent additions to the materia medica, inasmuch as Culpeper, the venerable "student in Physick," described it in his work published in 1650. This has been lately pointed out by a correspondent of the *Chemist and Druggist*, who gives the following extract: "The Way to make Œsipus — Take wool cut off from the neck ribs, and under the pits of the forelegs of a sheep not washed, but well wearied, wash it well in warm water so long till it have left all its fatness in the water, then press it out and lay it by, let that fat and foul water be poured from on high out of one vessel into another a long time till it be froathy, then let the froath settle, and take off the fat that swims at the top, then pour the water to and fro again, till neither more fat nor froath appears, then wash the froath with the fat in clear water till it be cleansed from the dross and will not bite your tongue if you touch it with it; then keep in a thick earthen clean pot in a cold place." —*Canadian Pharmaceutical Journal.*

EXPERIMENTS WITH THE VIRUS OF RABIES.—On March 6th a man in Brooklyn was bitten by a dog; on May 14th he died, with all the symptoms of hydrophobia. Portions of the brain and cord were sent to Dr. Sternberg, at Johns Hopkins University, and this gentleman on May 17th inoculated three rabbits with the tissue by Pasteur's method. On June 2d one of the rabbits showed symptoms of the hydrophobia of rabbits described by Pasteur; on June 5th the second rabbit showed similar symptoms. Some of the same brain and cord from the Brooklyn victim was taken by Dr. E. C. Spitzka, and rabbits were also inoculated by him. So far as we can learn from published reports, the rabbits showed symptoms like those of rabies, but Dr. Spitzka believes that such symptoms of themselves prove nothing, since he caused the same by inoculating rabbits with inert material and setting up meningitis.

THE MEDICO-LEGAL SOCIETY OF CHICAGO is the title of a new medical organization which starts off prosperously with a membership of over one hundred. The Society has this peculiarity, that while its objects are primarily the study of medical jurisprudence, it also intends to afford mutual protection against blackmail suits. If any member of this Society is blackmailed, the Executive Committee of the Society will investigate the case, and if the member is innocent, defend him at the expense of the Society till justice is secured. This also applies, of course, to any so called malpractice suits if the member is innocent.

THE VERMONT STATE MEDICAL SOCIETY holds its next semi-annual meeting at Burlington, June 24th and 25th. Dr. D. G. Kemp is President; Dr. J. S. Richmond, Secretary.

BEQUESTS TO HOSPITALS.—Mrs. Silas E. Burroughs, of New Haven, has given $5,000 to the New Haven Hospital to endow a free bed, which will be used more particularly for consumptive patients. The late Christian J. Hoffman bequeaths, upon the death of his wife, $5,000 to the Philadelphia Presbyterian Hospital, with $25,000 more in case the grandson die without lawful issue.

Reviews and Notices.

MONTHLY NURSING. By A. WORCESTER, A.M., M.D., Fellow of the Massachusetts Medical Society. 16mo, pp. 250. Boston: D. W. Mason. 1886.

THIS is a manual to be placed in the hands of anyone aspiring to care for a lying-in patient. Its substance has been given in a series of lectures to the nurses at the Boston Lying-in Hospital. The book is full of sound common-sense and confines itself strictly to its subject. Its brief, terse style is just the ideal one for a manual.

VENEREAL DISEASES. By BERKELEY HILL, M.D., and ARTHUR COOPER, M.D. 12mo, pp. 132. Philadelphia: P. Blakiston, Son & Co. 1886.

THIS is a student's manual by two well known London authors, who have written a more pretentious work on "Syphilis and Local Contagious Disorders." The present is the fourth edition of the manual, conformed in arrangement to the larger work. There is nothing particularly new set forth in the manual, which, however, is clearly written. The authors are dualists. They do not accept as clearly proven the causative relation of the gonococcus (Neisser) to specific urethritis.

FIRST ANNUAL REPORT OF THE MAINE STATE BOARD OF HEALTH, for 1885. Compiled by A. G. YOUNG, M.D., Augusta, Me., Secretary.

THIS is a most creditable account of the hygienic progress of the State. Reports are given from nearly every section, relative to epidemics, peculiarities of disease, etc. We congratulate the Board on the results of its work.

PROCEEDINGS OF THE MEDICO-CHIRURGICAL SOCIETY OF MONTREAL, 1883–85.

THIS is a neatly arranged and compact volume of nearly two hundred pages. It consists of the minutes of the Society's meetings during the years named.

LECTURES ON SYPHILIS. By G. FRANK LYDSTON, M.D., Lecturer on Genito-urinary Diseases, Chicago College of Physicians and Surgeons; Professor of Surgery in Chicago Dental College. 16mo, pp. 184. Chicago: A. M. Wood & Co. 1885.

THE title of this book sufficiently indicates the auspices under which its subject-matter was first made public. The whole subject is clearly set forth in accordance with the present views on the subject. In explaining pathological phenomena, the views of Otis are closely followed. Like all treatises built up from hospital and dispensary observation, it contains many practical points. While each subject is handled in a very instructive manner, the chapters on treatment deserve special mention. They cover all the ground, are elaborate in detail without useless verbiage, and show plainly that the author has a thorough practical acquaintance with the management of syphilis and its various complications, as well as of the needs of the student and practitioner of medicine.

PERIPHERAL ATROPHY OF THE OPTIC NERVE.—It is stated in the *Boston Medical and Surgical Journal* that Fuchs has concluded, from an examination of more than sixty specimens, of all ages, that in the human adult there is, as a rule, an atrophy of certain optic nerve-fibres. The fibres which are thus subject to a physiological atrophy are situated: First, immediately beneath the pial sheath of the nerve; second, about the central vessels which are accompanied, as is well known, by a continuation of the pial sheath. The degeneration is a species of gray atrophy, and is found, as a rule, after the thirtieth year. The functional consequence of this atrophy would, theoretically, be an enlargement of the blind spot.

Reports of Societies.

PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, April 2, 1886.

A. Brayton Ball, M.D., President *pro tem.*

Dr. Samuel Sexton reported a case of

COMPLETE FACIAL PARALYSIS OCCURRING DURING AN ACUTE CATARRHAL INFLAMMATION OF THE MIDDLE EAR.

The patient, Mr. McA——, a semi-public, forty years of age, never had robust health, but always subject to head catarrh, and of late years to neuralgia from the irritation of defective teeth. His present trouble began in November last, when the amalgam plug in the lower right second bicuspid tooth became loose, and was replaced by a dentist after the pulp and nerve had been removed from the tooth, leaving it in a diseased and sensitive condition. At this time the patient was run down, and the pressure of his work in assisting at the service of the Roman Catholic Church was very fatiguing. On Christmas morning last he got up feeling badly from an exacerbation of head catarrh, and during the church service, in which heavy vestments are worn, he perspired freely, and the right side of his neck and head, which were uncovered, were exposed to a draught of cold air from an open window. This was followed by subacute aural catarrh and severe neuralgic pains starting in the right mastoid, extending to the neck below, and spreading up over the temporal region. There was a heavy feeling in the ears, with tinnitus and deafness, which were believed to have been increased by the quinine administered. On the second day complete facial paralysis of the right side occurred. The pain in the right mastoid was so severe as to mask other symptoms, and to confine him to bed for three weeks. For several weeks after getting up the paralysis was treated with the faradic and galvanic currents, and the ear was blistered.

I first saw the patient on March 18, 1886, three months after the trouble began; he was pale, weak, and very nervous. He could speak, close the right eye, and control food during mastication better than at first, but still very considerable paralysis of all the muscles of expression remained. From the first there has been considerable swelling on the jaw over the region of the dead tooth, and the entire right cheek is more easily flushed than the left, the skin being hyperæsthetic and sensitive to the touch, especially in shaving. The drumheads now show but little of the effects of the recent catarrhal inflammation. The posterior segment of the right is clouded from previous nutritive changes, and the left has a manometric cicatrix in the posterior segment, a result of perforative inflammation in childhood. His hearing is almost normal in the right ear, but in the left a loud voice only is heard.

The anomalies of audition are particularly interesting, owing, it is believed, to the paralysis of the tensor tympani, stapedius, and tensor palati muscles, which derive their motor nerves from the facial, since it is through these muscles that tension of the transmitting mechanism of the ear is maintained. Since the paralysis came on, his own voice is unnatural to himself; it echoes in the right ear. Sounds emitted from the movement of heavy trucks, coal rattled in a sheet-iron vessel, the larger pipes of the organ and the like, or the voice when low in pitch, give rise to a second impression of sound which is perceived in another key altogether, and resembles the rattle of the cords of a snare-drum. This sensation is also caused by gently rubbing the head about the ear. This supplementary phenomenon, known as acusis duplicata, or double hearing, is due to cognizance being taken of vibratory movements of the drumhead itself, which occur independently of the rest of the transmitting mechanism, *i.e.*, without causing excursive movements in the chain of ossicles. The rattling of the drumhead, in fact, is heard as would be any membrane loosely stretched across the external auditory canal and made to vibrate. Autophonous phenomena are experienced in the left ear, due to the loss of tension from cicatricial transformation. Although low voice is well heard in the right ear for the most part, yet are interruptions frequent enough to cause great confusion.

In reviewing the history of this case it would seem that the nerves affected by the dental irritation were in an exhausted state favorable to neuritis, and that the facial nerve, which runs in the inner wall of the tympanum, sweeping over the round window before descending in the aqueductus Fallopii, was specially liable to become affected through extension of the inflammation of the middle ear present. It is difficult to say whether the exposure to the draught of cold air or the middle-ear disturbance, first gave rise to the nervous trouble; in other words, we cannot tell whether it was an ascending or descending neuritis. It seems probable, however, that but for the presence of the dead tooth the patient might have escaped the facial paralysis, since catarrhal inflammation of the middle ear is not liable to extend itself to the facial nerve; even the much-exposed *chorda-tympani* nerve seems seldom to be affected. There was in this case no alteration in sensation of the tongue.

We are not left in doubt as to the peripheral origin of the paralysis in this case, since the temporo-facial branch supplying the occipito-frontalis muscle was involved, and its fibres are believed to have a central origin remote from the other roots of the *portis dura*.

The value of pain in the mastoid as a symptom in differential diagnosis is well shown here. Intense and prolonged pain was experienced, due to the neuritis alone, in all probability, and hence the operation of trephining the mastoid for the relief of inflammation of the antrum or cellules would have been inadvisable.

On extraction the tooth giving rise to the irritation of the inferior dental nerve was found to have its pulp cavity carelessly filled with amalgam, and the canal of its root was loosely packed with cotton-wool down to within a quarter of an inch of the apex. The canal has an unhealthy look, and the alveolus was in a state of inflammation.

The patient has been treated by electricity, but not thoroughly, and blisters have been applied about the ear.

TWO TRACHEOTOMIES OF THE SAME DAY IN ONE FAMILY —WATER POURED INTO TRACHEAL WOUND TO ASSIST EXPECTORATION.

Dr. George F. Shrady referred to two cases of tracheotomy, which he had recently performed on the same day upon two sisters, aged respectively two and four years. He was called to them the day previous to the operations. They were both affected with diphtheria. In the younger the disease was in the fauces and extended downward, and in the older it was confined to the larynx and trachea. Both developed symptoms of suffocation rapidly.

The temperature in the younger child was 102° F., and in the older 101° F. The operations were performed without mishap—first upon the younger sister, and in a few hours after upon the older one. The younger although temporarily relieved of the difficulty of breathing, died of secondary croup twelve hours afterward. The older child recovered, discharging through the tube on the fifth day a bifurcated fibrinous cast. In neither of the cases was any chlorate of potash or iron administered, the treatment consisting in the freest possible stimulation by milk punch. The latter, he remarked, was his main-stay in desperate cases. This opinion was shared by Dr. Ripley, who kindly saw these cases in consultation, and assisted at the operations.

There was one item in the after-treatment to which he wished to call attention.

There was, as is usual, a great deal of expectoration through the tube, which was assisted by the inhalation of steam. But the most prompt benefit was derived from pouring lime-water by the teaspoonful directly into the trachea through the wound. This was done at the suggestion of Dr. Ripley, who had frequently used it in his practice with occasional good result.

Dr. Shrady had never seen this method tried before and was struck by its good effects in dislodging tough mucus and shreds of membrane.

Dr. Ball said he was unable to see how the lime-water could be of any special service, as it was expectorated so quickly, and thought that plain water would be equally as good.

Dr. Shrady said that so far as the mechanical effect was concerned, water would answer the same purpose. The possible advantage of the lime-water was that in case any was retained it might have the effect of loosening the phlegm or of possibly helping the separation of membrane.

Dr. Ball also referred to the temperature in Dr. Shrady's cases, and then said that the reason why he asked whether fever was noticed at the outset of the diphtheria of the larynx, no exudation being in the pharynx, was on account of a case at Bellevue Hospital, in which tracheotomy was performed, but the child died of extension of the exudation into the smaller bronchial tubes. Two or three days afterward a child in the same building—not in the same ward—was taken with what appeared to be a simple cold, attended by little or no fever; but in the course of forty-eight hours laryngeal stenosis developed, with scarcely any febrile disturbance, and they were inclined to regard the disease as catarrhal in character. The difficulty in breathing, however, increased rapidly, and tracheotomy became necessary. When the operation was performed there was slight fever, but it subsided entirely, and the tracheotomy gave the child complete relief from the distressing symptoms. The child seemed to get well. It remained without fever for ten days; but it was impossible to remove the tube on account of the difficulty of breathing which at once ensued. No membrane was expectorated during the next ten or twelve days, and they reached the conclusion that they had performed tracheotomy in a case of catarrhal croup. At about this time the child became feverish, and died within forty-eight hours. At the autopsy membrane was found commencing in the larynx and extending down to the small divisions of the bronchi.

The theory was that there had been diphtheritic croup in the larynx, which remained stationary after the tracheotomy for ten or twelve days, and then lighted up and extended into the smaller bronchial tubes. Dr. Jacobi had called attention to the fact that in catarrhal croup, when stenosis depended upon swelling of the mucous membrane, without false membrane, there is almost invariably more or less fever; but that in diphtheritic croup, when there was no false membrane in the pharynx, the case was very often unattended by fever; and that the absence or low grade of fever, combined with laryngeal stenosis, made it almost certain that new false membrane was present. The point was, that while fever attended laryngeal and tracheal diphtheria, cases died in which fever was *absent*.

The Value of Lateral Incisions of the vulva, for the purpose of preventing rupture of the perineum, is not generally conceded, but is apparently brought out by the recent investigations of Crede and Colpe. Out of 1,000 primiparæ in the Leipzig Maternity Hospital, incisions were not thought necessary in 741 cases, but nevertheless ruptures occurred in 104 of these favorable cases, that is, in fourteen per cent.; in the remaining 259 cases rupture seemed inevitable and the lateral incisions were made, with the result that the perineum was torn in 29 cases, or about eleven per cent.

NEW YORK ACADEMY OF MEDICINE.

SECTION OF PRACTICE OF MEDICINE.

A. L. Loomis, M.D., Chairman.

TRACHEOTOMY IN CROUP.

Dr. Alexander Hadden said he presented the paper as a continuation of one published in The Medical Record in 1880. He gave the histories of twelve cases in which he performed tracheotomy. The treatment, aside from the operation, consisted usually of an application of persulphate of iron and glycerine to the mucous membrane of the trachea at the place of incision, of slacked lime in the room, in some instances the use of a weak solution of bromine. In the diphtheritic cases the treatment was stimulating from the first.

Tracheotomy was followed in the first case with expectoration of membrane, relief to breathing, and the patient recovered. In the second case death took place eighteen hours after the operation of emphysema of the lung. The third patient died of emphysema of the lung twenty-four hours after the operation, having exhibited no diphtheritic complication. In the fourth case there was a thick, firm membrane of the tonsil and pharynx, evidently invading the larynx. The patient was given large doses of the tincture of chloride of iron and stimulants. Dyspnœa increased; tracheotomy was performed; the child did well for three days, but died on the fourth of bronchial obstruction and diphtheritic asthenia. The fifth patient was a boy, aged five, who had a croupy membrane of the tonsil extending upward into the nares and downward into the larynx. He was found walking about the room; the invasion was very insidious. Dr. Hadden placed him in bed, applied persulphate of iron and glycerine to the throat. Tracheotomy became necessary, after which the iron and glycerine was applied to the tracheal mucous membrane. Six days later the membrane had entirely disappeared. The tube was removed on the eleventh day, all signs of obstruction having disappeared. On the twelfth day there appeared albumen in the urine and paralysis of the muscles of deglutition. The patient died of paralysis of the heart. He had not received the nursing which he should have had, and death took place from causes not due to obstruction of the air-passages. The sixth patient died of pulmonary emphysema. The seventh patient recovered against their expectations. One other member of the family died from the disease. The eighth patient died, at the end of thirty hours after tracheotomy, of pulmonary emphysema and asthenia. The ninth patient had membranous laryngitis following measles, and died of broncho-pneumonia. In the tenth case he was called to perform tracheotomy when dyspnœa was extreme; the tube pushed the membrane before it, and the patient died on the operation-table. The eleventh patient died thirty hours after the operation of diphtheritic asthenia. The twelfth patient was seen with Dr. Reid; there was severe tonsillitis, no membrane was visible, and the temperature was 103° F. When Dr. Hadden arrived the child was cyanotic. Tracheotomy was performed. The lumen of the trachea was almost occluded. At first it was thought that a membrane was obstructing the tube, but examination of the trachea showed its mucous membrane to be smooth and the submucous tissue highly œdematous. Artificial respiration and irritation of the inner surface of the trachea enabled them, after about ten minutes, to bring about quite uniform respiration, and after about half an hour a very unpromising case was markedly relieved. The patient went on to recovery. The case was instructive because extremely rare. Dr. Hadden had never met with a similar one. It was evidently a case of œdema of the submucous tissue of the trachea, with but little catarrhal inflammation, and without any pseudo-membrane whatever.

It would be observed from the cases presented, that the author had made a distinction between croup and diph-

theria, and true membranous croup. He would not enter upon the question of the duality of these diseases further than to explain the details of his treatment. Many of the ablest authors at home and abroad held that where there was a pseudo-membrane diphtheritic inflammation was present. For the opinions of these gentlemen he entertained profound respect, but it seemed to him they were based more upon the revelations of histology than upon clinical phenomena. Pathology had not shown a difference between the lymph of varicella and small-pox, yet there was a vast difference between the two diseases. Clinically, croupous laryngitis and tonsillitis was markedly sthenic in character, non-infectious, of comparatively short duration, not leaving much constitutional disturbance. The disease began with marked symptoms; the temperature and pulse ranged high. Diphtheria, on the other hand, was asthenic in character. It might be in some cases ushered in with convulsions, followed by swollen tonsils, cervical glands, high temperature, but these were very malignant cases, as a rule; usually it began with general malaise, with fever, perhaps not higher than 100° F. So little was the throat affected that it was apt to be overlooked by the attendants.

It was important, according to the nature of the disease, whether a true croup or a diphtheria, to adopt an entirely different plan of treatment. The one called for treatment which was depressing in its effects, as cathartics, emetics; while the other, in its invasion and even at the height of its development, required stimulating and vigorous supporting treatment. Both required absolute rest in bed. If a child was attacked with croupy symptoms which he believed to be of a pseudo-membranous character, during the febrile stage he at first administered an emetic, afterward a calomel cathartic, and febrifuges of squills, aconite, or veratrum viride, as the case might be. On the following day, while the fever continued, he sometimes gave small doses of antimony. When the fever subsided he used iron and glycerine as a local application several times a day, continued until the exudation disappeared. If the croupy symptoms increased beyond a huskiness of the voice, he placed the patient under a steam tent. He gave a generous liquid diet, and kept the bowels free by a mild cathartic. Careful nursing, iron and quinine, constituted the main elements of treatment during convalescence.

On the other hand, if the case were one of diphtheria, he gave no depressants, but a mild cathartic, stimulants, iron and soda mixture, solution of bromine (Thomson's), the local application of iron; enjoined rest, kept the atmosphere moist with steam, because it was soothing to the air-passages, careful attention to the temperature of the room.

Dr. Hadden referred to the success which Dr. O'Dwyer had had with intubation of the larynx. Dr. Hadden had not yet employed the method, but he was disposed to think well of it from hearsay. His last twelve cases of tracheotomy had not been quite as successful as those already reported.

Dr. J. Lewis Smith opened the discussion with a brief paper on the local treatment of croup prior to the performance of tracheotomy. Alkaline inhalations had been in use in the treatment of croup as far back as the recollection of the oldest physicians extended. They had a solvent effect upon the fibrin of the croupous membrane. As water took up only a small portion of lime, it had been recommended of late years to increase the alkalinity, and to add to the alkaline medium the digestive ferment tripsin. If asked how to treat membranous or diphtheritic croup prior to a resort to surgical methods, Dr. Smith knew of nothing better than the constant or almost constant inhalation of the following: Tripsin, a quantity sufficient, or as much as could be added to the other ingredients without clogging the atomizer; bicarbonate of sodium, two drachms; lime-water, six drachms. The only objection to tripsin was its expensiveness. The result of the treatment of croup by inhalation depended to a great extent upon the earliness of its commencement. In his opinion the slight laryngeal catarrh which was the forerunner of croup might in a considerable proportion of cases be removed by inhalations, and the disease under discussion be prevented.

But if these slight symptoms passed unheeded, and inhalations were not used at the proper moment, and pseudo-membrane formed on the laryngo-tracheal surface, we all knew how incapable were inhalations of checking the progress of the membrane and of saving life. The physician was often not summoned until the disease had become fully established. One benefit of inhalations was that they rendered the muco-pus thinner, and they probably liquified the fibrin present in the pus.

Muriate of pilocarpin was recommended by those who used it in diphtheria, on the theory that by the abundant secretion from the surface of the air-passages which it caused it produced detachment of the pseudo-membrane. But, Dr. Smith said, it must be remembered that the expiration of the bronchial secretion was difficult in membranous croup, on account of the obstruction produced by the pseudo-membrane, so that pilocarpin was likely to cause filling up of the bronchial tubes, increased dyspnœa, and sudden death. This effect he had seen after the employment of pilocarpin, and warned physicians against its use.

Dr. Smith had been very favorably impressed with O'Dwyer's laryngeal tube for the relief of dyspnœa, and he had seen it rescue patients from impending suffocation in a number of cases of croup. Dr. O'Dwyer had spent some years in improving the instrument, and he now used one which seemed to be as nearly perfect as it could be made. It was not until recently that Dr. O'Dwyer had been made acquainted with the fact that Bouchut, in Paris, employed intubation of the larynx, and advocated its use in the place of tracheotomy, in 1858. Trousseau, being a great advocate of tracheotomy at that time, opposed the method, and the result was that a committee was appointed by the Academy, of which Trousseau was the head, and in their report they condemned intubation and recommended tracheotomy. The following facts relating to the use of O'Dwyer's tube could be considered as established: (1) the tube can be inserted in the fractional part of a minute, and can be removed in less than a minute; (2) in all cases in which the disease is confined to the larynx and trachea, it relieves dyspnœa as effectually and permanently as does tracheotomy; (3) in all cases of urgent dyspnœa or great prostration intubation is preferable to tracheotomy, since it can be quickly performed and without loss of strength accompanying hemorrhage; (4) the consent of the family can be obtained for tubage when they refuse it for tracheotomy; (5) there is no antagonism between tubage and tracheotomy, but tubage should precede tracheotomy, although the latter procedure was not likely to give relief when the former failed.

Dr. John H. Ripley said he had nothing very new to add on this subject. During the last six years he had made very little progress in the treatment of membranous croup; so far as he was concerned, the treatment was not any more successful that it was six years ago. Some epidemics had been more severe than others. His last fifty cases of tracheotomy had been more successful on the whole than the first fifty. In his first fifty about one in four patients operated upon recovered; during the last three or four years one in three and a fraction had recovered. He had done tracheotomy altogether one hundred and fifteen times. So far as he was able to judge, there had been no improvement in the general treatment except that patients got less medicine. In his last fifty cases he had given very little treatment aside from stimulants and nutrition. Formerly he gave chlorate of potassium very freely, but now he gave very little. Careful and continued examination of the urine of the

children showed that nephritis was a common complication, and he believed that chlorate of potassium was injurious in such cases. He thought it was injurious in small doses, and it was a well-established fact that it was a dangerous drug in large doses. He employed steam after the operation. He preferred simple steam to medicated steam. In one case in which he performed tracheotomy on a little child, the steam was medicated with a small proportion of carbolic acid. The mother thought that a little being good, more would be better, and they discovered that she had increased the quantity of the acid by the symptoms of poisoning which the child manifested. The patient finally got well.

Dr. Ripley was glad to see some support in the paper of his view, that children after tracheotomy for croup did not die of pneumonia. The author had said that five of the patients died of emphysema; Dr. Ripley thought it probable they died from extension of the membrane downward, producing emphysema. He supposed it was not the emphysema which caused death, for emphysema might exist indefinitely.

The author seemed to attach considerable importance to applications of persulphate of iron, in the belief that it prevented the formation of membrane. But if it prevented the formation of membrane simply at the point of application it would not do much good, for children did not die of membrane in the trachea.

The question of duality of croup and diphtheria had been up for discussion at almost every medical society in this city, and it was not necessary to discuss it this evening. He did not think the author had advanced anything which would go far toward settling the question. He said this with all courtesy to Dr. Hadden. It was said that in diphtheria there was a low temperature, and in croup a high temperature. Dr. Ripley had seen many cases of diphtheria in which, at the onset of the disease, there was a temperature of 104° or 105° F.

And regarding what the author called membranous croup, but what Dr. Ripley would call primary diphtheria of the larynx, the temperature ordinarily was not very high. After tracheotomy a high temperature was no proof of pneumonia; the child might die of secondary croup with a temperature of 105°, or with a temperature of 97°. He hoped to be able to demonstrate beyond contradiction, sooner or later, that it was bronchial croup which killed the majority of children who died after tracheotomy, and not pneumonia. Those opposed to him would call attention to, perhaps, little patches of pneumonia, but these would not produce death. It took a good deal of pneumonia to kill a child, as a rule.

Dr. Joseph E. Winters said he had not heard all the paper, but he inferred from the discussion that the author made a distinction between diphtheria and membranous croup. As Dr. Ripley had said, this subject had been extensively discussed in this city. Dr. Winters believed, from clinical and post-mortem examinations, that they were identical. We had no anatomical basis on which we could differentiate a membranous laryngitis due to cold and a membranous laryngitis of diphtheritic origin. If there was a membranous non-diphtheritic laryngitis, it could not be demonstrated clinically or pathologically from laryngitis of diphtheritic origin.

Dr. Winters believed that the extension of the diseased process into the larynx in diphtheria was only accidental; that it was not the natural tendency of the disease to spread into the larynx, but that such extension was due to exposure and the influence of cold. He had never seen a case of membranous laryngitis in the course of diphtheria which could not be attributed to cold or improper local treatment. As to local treatment, he did not believe it was curative; on the contrary, he believed that in a great many cases it was injurious. He was sure he had seen children recover after suspension of local treatment, who would have died had he persisted in the violent application of local measures which were so often used. The inhalation of the fumes of sulphurous acid produced a moisture of the throat and gave the patient great comfort, when a healthy person might find them very disagreeable. He thought patients did better with small doses of quinine and larger doses of iron than when they received nothing.

Dr. A. Jacobi asked Dr. Hadden whether he had meant to say certain of his patients had died of emphysema, or whether he did not mean of pulmonary œdema?

Dr. Hadden replied of pulmonary emphysema.

Dr. Jacobi would have to differ from him. When he found emphysema at autopsy, he would not claim that it had been the cause of death. He would say that it was only one of the consequences of the disease.

There was one fact spoken of by the author which was of great importance, namely, paralysis of the muscles of deglutition at an early period. Dr. Jacobi had seen a few cases in a long practice of paralysis of the muscles of the mouth, the result of œdematous effusion, and it was necessary to give food by a tube. When this condition arose there was great danger of food entering the air-passages and exciting a fatal pneumonia.

Another interesting fact was the case related by the author in which there was œdematous swelling of the submucous tissue at the seat of the operation which obstructed the tube. Dr. Jacobi had seen this condition very few times, and always with a considerable amount of pulmonary œdema. But he had never seen submucous œdema to such an extent as to contract the lumen of the trachea.

Again, the author had stated that in one case the membrane in the trachea was quite adherent. The stress which he failed to lay upon this fact Dr. Jacobi would now lay, for certainly when we opened the trachea and found a thick diphtheritic or croupous membrane that membrane was not usually embedded in the tissue. It swam, as it were, on the mucous membrane. This case offered stronger proof against the duality of the two diseases than the author had been able to bring in favor of their duality.

As to treatment, he would say that when steam was used it should not be produced by an alcohol-lamp or gas-jet, which burned up the oxygen in the room, but by a kettle on the fire, and conveyed through a cylinder under the bed-sheet surrounding the patient. He did not agree with Dr. Hadden that the temperature could be taken as in any way pathognomonic.

Dr. Jacobi related a case illustrating his statement that whenever one had a case of uncomplicated laryngeal stenosis, and no elevation of the temperature, he could feel satisfied that it was a case of membranous croup, and not of catarrhal or inflammatory croup. In inflammatory or catarrhal croup there was always elevation of temperature.

Dr. Henry D. Chapin would say a word with regard to tripsin, which he believed he was the first to use in croup. Certainly outside of the body it dissolved the membrane, and inasmuch as it was not irritating, he thought the fellows need not hesitate to use it through fear of doing harm.

Dr. Hadden, in closing the discussion, said that emphysema in the cases referred to was evident on physical examination. As to the use of persulphate of iron with glycerine, he was convinced of its benefit. There was a tendency for the membrane to extend from the tonsils down into the larynx, which he thought it tended to prevent. It constricted the capillary vessels, and enabled the mucous membrane to throw off the pseudo-membrane much sooner. It was not a painful application; it was soothing after being applied. He also believed in keeping the throat clean with a weak bromine solution.

Dr. Brown gave the result of intubation by O'Dwyer's method in twenty-five cases of membranous croup in the New York Foundling Asylum. In fifteen, which had already been reported in The Medical Record, there were four recoveries; since then it had been employed in ten cases with two recoveries.

The Academy adjourned.

MEDICAL SOCIETY OF THE STATE OF NEW JERSEY.

One Hundred and Twentieth Annual Convention, held at Sea Girt, N. J., June 8 and 9, 1886.

TUESDAY, JUNE 8TH.—FIRST DAY—AFTERNOON SESSION.

THE meeting was opened with prayer by the REV. DR. BROWN, who also made the address of welcome in a few happy remarks.

DR. PIERSON then made the report for the Committee on Credentials.

Dr. M. C. Hazen, delegate from Connecticut, and all other delegates, were invited to sit with the Society.

The minutes of the preceding meeting were read and approved.

DR. BALDWIN, Chairman of Committee on Business, reported the following subject for discussion at the next annual meeting of the Society, viz., "What is the Personal Experience in the Use of Antipyrine, and does it permanently Reduce Temperature?"

TREASURER'S REPORT.

Total receipts, $1,900.04; balance, $2,050.

The discussion was opened upon the results of the use of the muriate of cocaine in ophthalmic surgery, and also in general practice, as developed by the experience of individual practitioners.

DR. C. J. KIPP, of Newark, in speaking of

THE USE OF COCAINE IN OPHTHALMIC SURGERY

said he had used it in many operations upon the eye and had not been disappointed in its anæsthetic effect. He has, since its introduction, done away very largely with the use of ether and chloroform.

In cases of iritis it subdues the pain; in fact, in all painful affections of the eye he has found it of great benefit, especially when there is photophobia and lachrymation. In conjunctivitis he has not found it to be of much use. The doctor has not used it in enucleation of the eye. He has never witnessed any bad effects from its use.

DR. BOARDMAN REED, of Atlantic City, said it had been his experience that the persistent use of cocaine, in cases in which the mucous membrane was hypertrophied and congested, led to an exaggeration of the condition.

DR. KIPP said this result might be obviated by the use of caustic immediately after the application of the cocaine.

DR. OSBORNE, of Newark, had found it useful in allaying the pain of quinsy, and in rendering the tissues painless in small operations.

DR. PARRISH had used it in cases of melancholia, with apparent temporary effect. He had used the wine of coca with better success.

DR. WATSON had used it in a case of amputation of the thigh, injecting the cocaine at many points along the line of incision. While the patient suffered but little pain during the operation, his mental agony was distressing. Dr. Watson thought it unwise to employ cocaine in operations of such magnitude.

EVENING SESSION.

DR. JOSEPH PARRISH delivered the

ANNUAL ADDRESS OF THE PRESIDENT,

and took for his subject the

GEOGRAPHY OF MALARIA.

He said that to the unprofessional mind it means chill, fever, aching bones, creeping rigors, and all or either of the symptoms which announce the advent of the fever, whether it be ephemeral, intermittent, remittent, pernicious, or continued.

To the professional mind it covers a range quite as extensive, and is used with a vague and limitless meaning that is as surprising as it is groundless. The doctor questioned whether there was another word in the nomenclature of medicine that is employed in such a careless and indifferent sense as this single word *malaria*. For a number of years the doctor has thought that the phenomena of these fevers could be fairly accounted for without penetrating the realm of mystery or assuming the existence of an impalpable poison that has so far evaded the most thorough microscopic investigations and failed to disclose itself under the most rigid chemical analysis. He does not deny the existence of marsh poisons. On the contrary, he recognizes the fact that in the process of decomposition there is eliminated a variety of gases, either or all of which may be poisonous to human blood and tissue; but he did not feel relieved by this admission, for he is confronted by a stubborn fact which is the result of observation and experience during many years, and that fact is that similar, and even identical, effects are exhibited in localities where there are no paludal conditions and no chance even for poisonous exhalations from the soil. With such antagonistic conditions and the appearance of similar morbid phenomena the conclusion is inevitable that there is at least a lack of uniformity in the etiology of these fevers, which fact suggests the following inquiry:

If it can be shown that the characteristic chill, fever, and sweat, prevail in mountainous, rocky, and arid places, may not the marsh theory be excluded, even from localities where marsh is the prevailing type? In other words, if it can be shown that like symptoms can be traced to causes that are identical both in regions of mountains and rocks, as well as in delta and swamp, why need we resort to the inexplicable hypothesis of paludal miasm as the cause? It is generally admitted that what we recognize as malarial disorders prevail most extensively in hot climates, so that the focus of malaria may be said to be within the tropics. It should be remembered also that in such tropical regions the malarial type of disease is most apparent at those periods of the year when there is the most sudden transition from the greatest heat to the greatest cold.

DR. PRICE dissented from the views advocated by Dr. Parrish. He did not think that chill alone could be the cause of malaria.

DR. ROGERS considered it a mistake to say that an ordinary cold might be a cause of malarial manifestations. In genuine malarial fever (intermittent) there is a recurrence of symptoms, in the case of an ordinary cold there is none. In malarial fever the symptoms recur after the effect of the medicine has gone.

DR. STEVENSON argued against Dr. Parrish's theory, stating that on the Atlantic slope of New Jersey, south of Burlington County, for a distance of about forty miles from the coast, there was no malaria, while in the section of country adjoining on its western side, and south of Camden County, there is a great deal of malaria.

DR. B. REED, of Atlantic City, thought the cases of "malaria" reported as developing at Atlantic City were misnamed. He considered all the cases due to sepsis, or to the influence of typhoid-fever poison.

DR. FISHER spoke in favor of the marsh theory.

DR. BENJAMIN spoke of newly upturned earth as a cause.

DR. T. J. SMITH, Chairman of the Standing Committee, reported upon

THE HEALTHFULNESS OF THE VARIOUS COUNTIES.

In Essex County epidemic influences have been felt during the last year. In Newark there have been many cases of diphtheria and croup. In Atlantic County throat and lung diseases have prevailed. In Mercer County there have been quite a large number of cases of scarlatina, diphtheria, and typhoid fever. In Middlesex County dysentery has been prevalent. In Monmouth County there was quite a severe epidemic of measles. In Salem County a more than usual amount of alimentery disorders were observed. In concluding

his report he stated that there has been less sickness in the State than in several years. Malarial fever is becoming more rare each year.

Fevers have been moderate in amount, and singularly governable by treatment. The ordinary endemics—rubeola, whooping cough, and parotitis—were less frequent and of milder type than in years past. Diphtheria has been restricted in its prevalence to a few localities. Scarlet fever was less in amount, and did not present any striking features. A limited number of cases of puerperal fever have been reported. There have been a few cases of cerebro-spinal meningitis. The State has been almost exempt from small-pox.

Dr. Elmer, Corresponding Secretary, then made his report.

Wednesday, June 9th—Second Day—Morning Session.

Dr. Godfrey, a delegate to the American Medical Association, gave a very interesting report of that Association.

Dr. E. M. Hunt moved that so much of the report as did not refer to the suggestions of the St. Louis Society be accepted. His motion, after considerable debate, was carried.

Dr. W. B. Bronson and M. C. Hazen, delegates from Connecticut, made a few congratulatory remarks, which were acknowledged by Dr. Parrish.

Dr. H. Genet Taylor made a report on

MEDICAL EDUCATION.

He said that a casual glance at the history of the New Jersey Medical Society, and a retrospective view of the past seventy years, and particularly the original Act under which this Society was incorporated, is conclusive evidence that in order to elevate its standard, and to guard against the evils growing out of a want of knowledge of our science, the Legislature of New Jersey conferred upon us certain sacred trusts, to protect which, we, as successors of the handful then composing our Society, are bound by every principle of honor. In the supplement passed two years later, the same ideas were again promulgated, and further powers given to carry into effect the original object of corporation. Under this Act and supplement the Society worked successfully until empiricism and quackery began to assume gigantic proportions, when, in order to better protect the rights conferred under the original Act, relief was again given in the Act of 1830, which Act, if in force to-day, would guard our thresholds and place the medical profession in New Jersey beyond the reach of impostors and those unworthy of the honors of membership. In the year 1864, when surrounded by many difficulties at almost every step, we concluded to surrender all our remaining rights to the State, and organize under a comparatively new law which was then passed, but which confers few powers beyond ordinary corporation privileges. So now to-day, with a large increase in our membership, and a much larger one in the form of quackery and illiterate pretenders of the healing art, we cannot claim that protection conferred fifty-six years ago by the Act of 1830, and, unless an effort is made, or some action taken to reform our present system, I feel the day is not far distant when the Medical Society of New Jersey will exist only in name. The doctor urged that the student of medicine should be possessed of knowledge sufficient to make an impression on the popular mind. He should devote himself in his early years to the study of the classics, to researches in metaphysics, mathematics, and natural sciences, for, as Bishop Barclay justly says, "that it is of the number of those preparatory studies which may be compared with crops raised, not for the sake of the harvest, but to be ploughed in as dressing to the land." He further said that "that rivalry between schools which should lead to constant efforts to elevate the character of medical instruction, and to raise the moral value of the diploma as a certificate, has been perverted, under the influence of this mistaken system, to results precisely opposite."

Dr. W. K. Newton, of Paterson, N. J., read a very interesting paper on

THE RELATIONS OF THE PHYSICIANS TO THE STATE.

He said that while the physicians of to-day know more about disease, its causes, pathology, and treatment, than ever was known before, they do not, perhaps, exercise the same therapeutic instinct possessed by their fathers. Much may be learned by observing the habits and practice of our ancestors in medicine. If they were less scientific than are we, they were nearer to the hearts of the people, were oftener sought to counsel in the affairs of State, and had more influence in political life. Dr. Newton emphasized the fact that the physicians do not show sufficient interest in the affairs of the State. He said that the doctor should be found (as an interested party) in the front rank, and not behind, shirking his duty. He would not have the doctor converted into a political wire-puller, for then he would be a hybrid, but he would have him take such a personal interest in the political affairs of the State as to at least make an effort to clarify the present unclean condition of State politics. He then pointed out some of the exemptions granted to the doctor by law, also the duties imposed. He also stated that a physician as an expert cannot be forced to testify unless compensated; further, that as an expert he may state conclusions and hypothetical facts, whereas an ordinary witness may state only facts.

DISCUSSION UPON THE REPORT OF THE COMMITTEE ON EDUCATION.

Dr. T. J. Smith thought that while it might be desirable for some reasons to urge the acceptance of the recommendation of the Committee, for certain other reasons it might not be practicable. He thought that the young men anticipating the study of medicine would conclude to go to one of the colleges in New York or Philadelphia, and thus escape the provision made in their behalf by the New Jersey Medical Society. As a member of the Committee he would not urge its acceptance, if it could be shown to be impracticable.

Dr. Benjamin thought we should consider the interests of mankind rather than the pecuniary interests of the colleges, and would therefore urge the acceptance of the recommendation of the Committee.

Dr. Sehlbach, in a very positive manner, objected to a part of the recommendation, namely, that every person contemplating the study of medicine shall be able to translate with facility three books of the "Commentaries" of Cæsar, "two Orations" of Cicero, and two books of the "Æneid" of Virgil; Greek language, including its grammar, the "Anabasis" of Xenophon, and two books of the "Iliad" of Homer. Dr. Sehlbach considered it unnecessary to be able to translate so much of Latin and Greek in order to begin and successfully complete a medical education. He thought the elements of physics, chemistry, and natural history, including botany and zoölogy, were far more important. As a method of annihilation he considered the course proposed by the Committee a good one, for it proposed to allow Xenophon to knock the trembling applicant down, Cæsar to kick him out of the window, and Cicero to trample upon him. He therefore urged that the further consideration of the question be indefinitely postponed.

Dr. Rogers thought that Dr. Sehlbach would annul all law and order, and institute a pernicious individual liberty. We should create a healthy public sentiment upon this point, and elevate the standard of medical education by careful preliminary instruction. He claimed that unless a student understood Latin he could not fully understand his own language, and therefore but imperfectly grasp the meaning of the terms so frequently used in every text-book and every lecture.

Dr. Pennington fully endorsed Dr. Rogers' views, and opposed Dr. Seabach's sentiments in a very emphatic manner. He considered the classics as essential if the mental faculties are to be properly trained and developed.

Dr. G. H. Ballery then read an unusually instructive paper on

ABDOMINAL SURGERY.

He cited many cases which had come under his own observation, and which were replete with information and points of interest.

OFFICERS ELECT.

The Nominating Committee next made the following report :

President—C. J. Kipp.
First Vice-President—J. W. Ward.
Second Vice-President—H. G. Taylor.
Third Vice-President—B. A. Watson.
Corresponding Secretary—Wm. Elmer.
Recording Secretary—Wm. Pierson.
Treasurer—W. W. S. Phillips.
Standing Committee—T. J. Smith, E. S. Marsh, D. C. English.
Delegates to American Medical Association—E. North, J. W. Ferry, D. Benjamin, C. R. Wiley, C. J. Kipp, John Ashcroft, W. P. Watson, D. C. English, H. J. Cook, S. H. Reed, A. W. Rogers, W. S. Ewen, W. J. Swinton, J. Miller, S. W. Oakley, J. Parrish.

Dr. Benjamin then offered the following resolution, viz., that the New Jersey State Society recommend only such colleges as have preliminary examinations and a three years' course.

Approved.

Dr. Wittingham offered a resolution

ON EXPERIMENTAL RESEARCH AND VIVISECTION

in the following form :

Whereas, In the investigation of questions pertaining to life, health, and disease, experiments upon lower animals are absolutely necessary to determine the causes and results of diseases or injuries ;

Resolved, That this Society not only countenances but approves of such experimental research, and disapproves of the action of societies or persons who, on the ground of preventing cruelty to animals, would throw obstacles in the way of experiments having for their object the relief of human suffering.

Approved.

The next annual meeting will be held at Beach Haven, N. J., in June, 1887.

MASSACHUSETTS MEDICAL SOCIETY.

One Hundred and Fifth Anniversary, Held at Boston, June 8 and 9, 1886.

TUESDAY, JUNE 8TH—FIRST DAY.

The fellows made the usual visits in the morning to the Massachusetts General, the City, and the Children's Hospitals.

During the day Dr. Ernst exhibited, at the Harvard Medical School, apparatus for bacteriological research, with cultivations and microscopic preparations. At the Institute of Technology there was an exhibition of drugs.

At 2 P.M. the members met in Huntington Hall, and listened to a paper on

THE ABUSE OF MEDICAL CHARITY ;

A Remedy applied in 3,000 Cases of Out-door Patients, Results, by Dr. Frederick F. Daggett, of Boston.

Dr. Doggett spoke of the well-recognized abuse of medical charity, and described his plan for its prevention. This consisted in a systematic investigation of the worthiness of applicants, and had, as shown by the writer's statistics, resulted in a large decrease of the number of unworthy applicants.

Dr. John L. Hildreth, of Cambridge, read a paper entitled

[illegible] THE LAW RECENTLY ENACTED IN [illegible] TO PREVENT THE SPREAD OF [illegible] DISEASE ?

The conclusion of the paper was that the spread of the contagion had probably been prevented, but the doctor stated that, were he to criticise the rules, he would say "they were not definite enough where the law says," in regard to the dangers of contagion, "two weeks from the recovery of the last case." "Physicians have different notions as to where, in the ordinary cases, recovery begins."

PAPERS READ.

"The Present Status of Bacterial Pathology" was next considered in an interesting paper by Dr. Albert N. Blodgett, of Boston ; followed by one on "The Management of Cases of Rigidity of the Os Uteri in Labor," by Dr. Wm. E. Boardman, of Boston.

Dr. Charles Harrington, of Boston, then read an interesting paper upon

A NOT WELL-RECOGNIZED SOURCE OF DOMESTIC POISONING, WITH CASES.

The essayist said that bichromate of potassium is now regarded as by far the most useful mordant for the manufacture of woollen goods, but that it was a poison. Several cases were cited in support of this theory. One was that of a strong, healthy woman who worked on cloth such as is used in making boys' caps. Her symptoms were intense itching of the head and body, cutaneous ulceration, and the loss of six finger-nails. Other cases cited were those of two young boys and an aged clergyman, who experienced similar symptoms, all of which the essayist attributed to the wearing of clothing and gloves made of materials in which bichromate of potassium was used as a mordant.

The final paper was upon "Abdominal Cellulitis," by Dr. Julian A. Mead, of Watertown.

The Annual Conference of Censors was held at No. 19 Boylston Place, at half-past two o'clock. Routine business only was transacted.

THE ANNUAL MEETING OF THE COUNCILLORS

was held at No. 19 Boylston Place, at 7 P.M., President Charles D. Homans, M.D., in the chair. There have been 35 deaths the past year, and the gain has been about 78, the present membership being about 1,675. The diplomas of 24 additional colleges have been recognized during the year. The Society's financial condition is good. The following officers were elected for the ensuing year : President, Thomas H. Gage, of Worcester ; Vice-President, John M. Harlow, of Woburn ; Treasurer, F. W. Draper, of Boston ; Corresponding Secretary, C. W. Swan, of Boston ; Recording Secretary, F. W. Goss, of Boston ; Librarian, E. H. Brigham, of Boston ; Orator, G. H. Townsend, of South Natick ; Anniversary Chairman, W. L. Richardson, of Boston.

WEDNESDAY, JUNE 9TH—SECOND DAY.

The annual meeting was held in Huntington Hall at 9 A.M.

President Charles D. Homans, M.D., of Boston, in the Chair.

The records of the last annual meeting were read by the Recording Secretary, Dr. Francis W. Goss, of Roxbury, and were approved by the meeting. There have been 78 new fellows admitted to the Society during the last year, and 31 have died. The Treasurer, Dr. Frank W. Draper, of Boston, presented his report, from which the following figures are gleaned : Last year's bal-

ance, $1,710.73; total receipts, $10,452.40; total expenditures, $8,685.03; balance this year, $1,767.37; total balance, $3,478.10. The invested funds are $32,420.17, bearing interest at the rate of four per cent. Thirteen members of the Society have forfeited their membership by removal from the State or failure to pay their assessments. The names of three fellows have been dropped from the rolls on account of delinquency in payment of fees. There are now 1,605 fellows in the Society.

The following papers were then read: "An Epidemic of Malaria in Eastern Massachusetts in 1885," by Dr. Zabdiel B. Adams, of Framingham; "The Causation and Treatment of Lateral Curvature," by Dr. Edward H. Bradford, of Boston; "Some of the Results of Fractures," by Dr. Joseph E. Garland, of Gloucester; "The Etiology and Treatment of Summer Diarrhœa of Infants," by Dr. Henry C. Haven, of Boston.

After the reading came the introduction of delegates. This was followed by an intermission of fifteen minutes, and then the orator, DR. RICHARD M. HODGES, of Boston, delivered the annual discourse, upon

UNDERCURRENTS OF MODERN MEDICINE.

The discourse, which occupied about an hour in delivery, was one of the greatest excellence, and showed a close grasp upon, and a thorough knowledge of, the various branches of the subject treated on the part of the writer. The orator was rewarded with the closest attention of the Society throughout the entire delivery of the discourse, each good point was received with appreciative recognition, and as he closed there was enthusiastic and prolonged applause.

The President-elect, DR. THOMAS H. GAGE, of Worcester, then made a short speech of thanks.

At the close of Dr. Gage's speech, the procession of the Fellows, formed in the order of seniority, proceeded to the Clarendon Street Skating Rink, where, at half-past one o'clock,

THE ANNUAL DINNER

was served. Anniversary Chairman Dr. Edwin B. Harvey, of Westbury, presided, and made the opening speech. On his right, in the order here designated, sat the retiring President, Dr. Charles D. Homans, President-elect Gage, Dr. John M. Harlow, Dr. B. E. Cotting, Dr. H. W. Williams, Dr. H. P. Walcott, and Surgeon-General Holt. On his left were President Pillsbury, of the State Senate, Dr. Gerrish, Dr. Lyman, Rev. Minot J. Savage, Dr. Hartnell, Dr. R. M. Hodges, and Dr. George W. Gay. The divine blessing was invoked by Rev. M. J. Savage, after which about an hour was spent in discussing the dinner. During the dinner, and at intervals during the speaking, the Germania Orchestra rendered pleasing musical selections.

The toast "The Massachusetts Medical Society" was responded to by PRESIDENT-ELECT GAGE.

In the unavoidable absence of Governor Robinson, HON. ALBERT E. PILLSBURY, President of the State Senate, was introduced to respond for the Commonwealth, and was received with loud applause. After a few facetious references to the presence of lady members, misnamed "fellows," and to the infallibility of the Legislature, he took up the subject of the State Board of Health, Lunacy, and Charity.

The REV. MINOT J. SAVAGE, of Boston, followed with some remarks on the parallels suggested to him between the medical and clerical profession.

DR. GEORGE W. GAY, of Boston, then read a poem written for the occasion by Mrs. M. E. Blake.

The last speaker was PROFESSOR JOHN HARTNELL, of Johns Hopkins University, who made a strong plea in behalf of physical culture and hygiene in schools and colleges; after which the exercises were brought to a close, and the one hundred and fifth anniversary of the Society ended.

Correspondence.

"IS DISEASE OF THE UTERINE APPENDAGES AS FREQUENT AS IT HAS BEEN REPRESENTED?"

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I have just read in your issue of April 10th the report of a paper by Dr. Henry C. Coe on the question, "Is Disease of the Uterine Appendages as Frequent as it has been Represented?" This title is to me a most extraordinary one, because I do not know that anyone has attempted to make any representations as to how frequent the disease may be, and when people talk about its extreme frequency they mean, of course, only its relative frequency. It is more frequent in my practice than in the practice of anybody else, simply because patients are sent to me from all over the world with the various forms of this disease for treatment.

I have not the pleasure of knowing who Dr. Henry C. Coe is, but I must ask you to allow me to ask his authority for two statements which he fathers upon me. He says that he is not "prepared to accept the statement of Mr. Tait that it was illogical to attempt to make a differential diagnosis between certain conditions, and, on the contrary, he believed that it was illogical not to attempt to separate the different classes of cases." I want to know where in all the writings that I have issued on this subject this statement is to be found, for I cannot find it. Again, I want to know how Dr. Coe justifies the following sentence, "That against the sweeping statement made by Mr. Tait, that in chronic inflammatory disease of the ovaries the tubes were invariably involved, Dr. Coe protests." I should like to know where in all my writings Dr. Coe finds this statement, for I cannot find it.

My friend, Dr. Lusk, says "that he had a suspicion that even Mr. Tait did sometimes remove ovaries and tubes which might have been properly included among the healthy." I want to know Dr. Lusk's authority for this statement. I protest that his suspicion is groundless.

Dr. Lusk says "that the theory that the abdominal cavity should be opened in doubtful cases was at the bottom of the mischief which the paper was intended to combat." Will Dr. Lusk tell us who has ever propounded or supported such a theory of foolishness, or will Dr. Lusk give up talking in this slipshod way and confine himself to exact utterances?

What I presume he meant was what has been termed "Tait's Law" by my friend, Dr. Joseph Price, of Philadelphia, and the words of which he has quoted with scientific accuracy, and not with the dimness of memory evinced by Dr. Lusk: "That in every case of disease of the abdomen or pelvis in which the health is destroyed or life threatened, and in which the condition is not evidently due to malignant disease, an exploration of the cavity should be made." Like Dr. Price, I think this is a matter to which everyone must be a convert, but they must not pervert it by alterations or suppressions such as Dr. Lusk has been guilty of; at any rate, if they do, they must be kinde nough to leave my name out of the discussion. I will not accept the paternity of such nonsense.

The harm that has been done, and there can be no doubt great harm has arisen, has come entirely from slipshod readings of this law, and not from its observance. Dr. Lusk is an example which all wise men will do well to avoid. I am, sir, etc.,

LAWSON TAIT.

BIRMINGHAM, May [illegible].

ABNORMALITIES AND SURGICAL OPERATIONS UPON THE VISCERA.—The occasional absence of one of the kidneys was recently the cause of a fatal result from nephrectomy. During a course of operative surgery at Vienna, the operation of left lumbar colotomy was performed, and transposition of the viscera was found.

ON FATTY AND SARCOMATOUS TUMORS OF THE KNEE-JOINT.[1]

By ROBERT F. WEIR, M.D.,

PROFESSOR OF [illegible]

In 1883 a young man presented himself at my clinic, at the College of Physicians and Surgeons, for the treatment of an affection of the knee-joint which had existed for nearly three years, and which did not result from any injury that he could recall. The joint was found moderately distended with synovial secretion, and was somewhat tender to the touch. He stated that this swelling diminished on several occasions by rest and by the use of an elastic bandage, and would suddenly recur, but without symptoms of interarticular "catching." On further examining the joint a mass of considerable firmness, like an ordinary loose cartilage and the size of an almond, was felt on the inner side of the patella. This could be moved up and down and crowded under the patellar ligament, and by pressure caused again to emerge, but it was evidently pedunculated, as it could not be forced into other superficial parts of the joint. He was sent into my wards at the New York Hospital, and under ether, October 13th, an incision two inches long was made down to the supposed cartilage. On nearing the capsule the increasing softness of the mass was observed, and when it was exposed it proved to be a portion of fatty tissue, harder than usual, and attached by a rather broad and thick pedicle, which stretched under the *ligamentum patellæ* and across the joint. As this mass could be pulled out with moderate traction, an attempt was made, in addition to the removal of the button-shaped end, to cut off, after ligating it, as much of the lipomatous growth as was possible. To accomplish this, even imperfectly, an unusual amount of manipulation of the joint occurred. To obviate the possible ill effects of this, the cavity of the articulation was washed out with a sublimate solution of 1 to 2,000, a drainage-tube inserted, an iodoform and sublimate dressing firmly applied, and the limb finally secured on a posterior splint. Notwithstanding the whole operation had been conducted on carefully carried out antiseptic precautions the case went to the bad. On the fifth day suppurative synovitis had set in, for which the joint was freely opened on the other side and drained. A hygroma over the internal hamstring, which was noticed to fill and empty as the joint was washed out, also required opening to evacuate the pus which the joint-drains did not control, and this was, in all probability, the starting-point of the extra-capsular abscesses which eventually riddled the popliteal space and calf of the leg. A vain attempt to save the limb terminated, November 27th, in an amputation of the thigh in its middle portion, which was closed by Neuber's deep occlusion method, with the result of entire primary union, so that the patient was able to walk about on crutches eighteen days after the last operation. The tumor removed was pink in color, with an irregular surface, and according to the report of the pathologist of the hospital, Dr. Peabody, was of the consistency of heart muscular tissue. Microscopically it was found to be made up of very vascular connective tissue, rich in fat and connective-tissue cells.

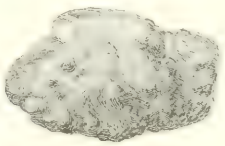
It cannot be doubted that the treatment of the case would have been more surgically correct had less been done to the fatty mass extending under the patella, and had also drainage been then made through the hygromatous pouch on the posterior aspect of the limb. The novelty of each of these conditions contributed to the errors, which should be kept in view in similar cases.

A case, very like the above, a few months later, came under the charge of my colleague, Dr. William T. Bull, and was as follows: Alice B. B——, aged twenty-four, entered the New York Hospital, March 2, 1884, for pain, stiffness, and swelling in the left knee, which had lasted over a year, and for the production of which she could assign no cause. She could always flex and extend the limb, and had not experienced any sudden catch or pain while walking, though several times, when quiet, she had seizures of short, sharp pain on the inner side of the joint. Seven months previously a painful lump had been recognized in the knee. On examination this was readily detected internal to the patella and was of the size of a large bean, hard, and movable for about an inch, parallel to the axis of the limb. Moderate joint effusion coexisted. Under a carbolic spray the joint was opened, April 3d, over the tumor, by an incision two inches long, the tumor exposed and lifted out, and its slender pedicle ligated and cut off. The wound was not sutured. Iodoform and sublimate dressings were tightly applied and the knee immobilized by a plaster-of-Paris dressing. The patient progressed satisfactorily. The dressings were removed at the end of a week, and she left the hospital on the eighteenth day. She was seen again May 15th, walking satisfactorily without pain and swelling, and only feeling a little weakness in the joint. The tumor was reported by the pathologist of the hospital to be composed chiefly of small, round, and spindle cells, with a minimum amount of intercellular tissue; also many giant-cells, much blood-pigment, and a few good-sized blood vessels; he therefore gave the diagnosis of a sarocma with giant cells.

A few days after this case Mr. William P——, aged thirty-nine, was sent to me by Dr. Henry F. Walker for relief from a loose cartilage in his left knee joint. I had seen this gentleman two years before, and advised then the removal of a movable body from his joint, which he stated had at that time existed for three years, and which came without any injury, inconvenienced him but little, save after dancing, to which amusement he was much devoted. The mass was then about three-fourths of an inch in diameter, but its motion was quite limited in area. The pain that he felt was variable and at no time great, nor was it associated with any distention of the joint. He declined any surgical interference at that time. Within a year subsequent to his last visit to me he had much more uneasiness, and occasional painful fixation of the articulation, which would prevent his walking for a day or two, but which apparently produced no effusion. I found that the supposed loose cartilage had much increased in size, and that its excursions were greater than when I had last examined the knee, though they were still limited to the inner side of the joint. On April 19, 1884, under a carbolic spray and full antiseptic precautions, I cut down on the tumor, which was held for me by an assistant, and brought into view an irregularly shaped, softish growth, yellowish-pink in color, and marked by sundry ecchymotic patches on its surface, the

[1] Read at a meeting of the Practitioners' Society, held May 7, 1886.

latter evidently the result of prolonged terpsichorean efforts made a few evenings before. This mass was held by a long, slender pedicle which was tied and subsequently divided. The ligature of catgut, however, slipped, and allowed some two or three ounces of blood to be extravasated into the joint cavity. This was evacuated by pressure over the knee, and the hemorrhage checked by a continuance of the same for five or six minutes. In consequence of this mishap, instead of simply leaving the wound open, a drainage-tube was inserted, and the usual iodoform and sublimate dressings applied, and the limb placed at rest in a posterior splint. The tumor removed (see diagram) was one and one-half



inch long by one inch broad, and nearly three-fourths of an inch thick. It looked like an ecchymotic mass of fat, but its microscopic examination by Dr. Peabody showed it to be formed of connective tissue, containing in its meshes a great many round and spindle cells and much blood pigment. He classed it as a fibro-sarcoma. The recovery was uninterrupted. On the third day slight elevation of temperature took place, and on removing the dressing it was seen that choking of the egress of synovial secretion had been occasioned by the ordinary iodoform gauze used (which I have since abandoned from this and similar experiences). On its removal several ounces of clear synovia escaped, and the dressings were reapplied, with iodoform merely dusted on the sublimate gauze, with rapid restoration of the normal heat. The wound was found closed in a week. At the end of the third week the patient was going about. He has been frequently seen since, and his joint functions are fully restored, and no sign of local or other recurrence has been observed.

The rarity of both of these varieties of movable bodies in the knee-joint is great, and concerning those having sarcomatous elements I can find, in a fairly extended search, but one other case, and this is reported by Simon.[1] It was met with in a man, forty-six years of age, who had had an impaired knee-joint for over six months. On the inner side of the knee was felt a mass the size of a patella, which was cut down upon and extracted after division of its broad base. It was attached to the outer side of the patella. Full restoration of the joint-functions took place. The tumor, 5 ctm. in diameter and 1½ ctm. in thickness, was smooth and shining, and in color a whitish-red. In consistence it was soft and somewhat elastic, though in the interior were perceived hard masses the size of peas. Under the microscope the tumor was covered with epithelium, and its substance, rich in vessels, consisted of many spindle- and irregular-shaped cells, with oval nuclei and with occasional fatty cells. Blood extravasations were dispersed throughout the tumor. Besides these were found large, irregular-rounded, or slightly angular cells, as is found in sarcomata. Simon called this tumor a hypertrophied sarcomatous synovial fringe, and gave illustrations of the mass, gross and microscopical, which latter sustain his diagnosis. But of the lipomatous growths there are a number (eight[2] besides my own) on record. Volkmann[3] reports a case in a man, sixty-three years of age, which had lasted a year and a half. It produced occasional severe pain, though the catching between the bone-ends was not distinctly marked. It was removed under spray, with prompt recovery. The mass was the size of a cherry. The same author[4] gives a drawing of a remarkable fringing, about the patella and periphery of the joint-capsule, of fatty masses in great number, but of small size, taken from the case of J. Müller. König[5] states briefly that he had operated on two cases of such fatty tumors, one of which was of traumatic origin.[6] Barwell, in his work on "Diseases of the Joints,"[7] gives a noteworthy case, where two pedunculated fatty masses were removed from the same knee-joint, one of which was over the outer end of the bone, just above the patella, both only slightly movable, and associated with marked hydrarthrosis. They were, after removal, in shape like an oyster, lipomatous in character, and each about one and a half inch long. Recovery was perfect. No traumatism was recognized in the history of this case. Schmolck[8] has very recently published two additional cases of fatty tumors in the knee-joint, which have the interesting accompaniment of a synovial tuberculosis attached to them, but apparently without any causative action. The first of these was encountered in a man, twenty-three years of age, of good health and no tubercular history. His right knee-joint had been the seat of slight, repeated inflammation for years. In 1880 he was treated for hydrops articuli. In 1883, after active gymnastic exercise, he had severe pain in the joint, and after that time two small, rather movable soft bodies were felt in the joint. This was opened by Schmolck by a long cut on its inner side, for the treatment of what was considered a tubercular synovitis, but no discharge of fluid took place, but a prolapse of a large number of fringe-like masses, some of them of the size of the end of the thumb. A number of these which rested on the anterior surface of the femur were cut off with free hemorrhage. Besides this mass three others, larger and more polypoid, were found and removed by a separate incision on the outside of the joint. Antiseptic washing out, drainage, and dressing employed. Six weeks after the wound healed, which occurred promptly, the patient could bend the limb to an angle of 120 degrees, and was rapidly improving; could then walk without limping, and rapidly. Over the surface of these tumors were seen very many slightly defined pearl-gray dots. These miliary deposits were also seen over the portions of the synovial membrane which had been cut away. Microscopically the smallest fringe showed a slight fibrinous skeleton, with spindle-, round-, and star-shaped cells, and in these the fatty tissue was but small. In the larger masses this latter tissue was the main constituent. In some of the larger miliary deposits giant-cells were seen, with occasional bacilli in them.

The second case reported by the same observer occurred in a man, fifty-two years of age, without tubercular antecedents, whose right knee-joint, from a strong exertion, became slowly enlarged with synovial effusion, but no symptoms of joint-locking occurred. Several soft, flabby masses could be distinguished, one as large as a twenty-five cent piece. The articulation was opened on each side of the patella, and after the escape of the synovial fluid many deep red folds projected into the wound, studded with multiple grains of minute size. The rest of the capsule was also much thickened. These masses were removed by scissors and scalpel, and the joint thoroughly washed out with an antiseptic solution. Improvement, but not a cure, followed. This was apparently a case of thickening, from a rather early treated tubercular synovitis, as bacilli were found microscopically, and it should hardly be classed, as Schmolck does, among the lipomatous growths, for such swollen synovial projections are not infrequently seen even in uncomplicated traumatic synovitis.

Barwell assigns, as a mode of production in such cases, that fatty and other formations may project farther and

farther into a joint, and, by a kind of hernia inward, may be transformed from an extra-articular to an intra-articular situation. A glance at the admirable plates (Nos. 32 and 35, pp. 350 and 365) in Morris' work on the "Anatomy of the Joints," 1879, will show how readily this can happen with the fatty tissue beneath the *ligamentum patellæ*, and also how such lipomatous tumors can be developed elsewhere in the folds of the synovial membrane, which often normally contains an appreciable amount of fat. Volkmann also presents the same explanation, and König remarks that the retro-capsular space above the condyle is frequently the site of fatty deposits, and which might be the genesis of lipomatous joint tumors. I should judge that this etiology will be accepted in connection with those cases where the element of traumatism is absent. But an injury, when developed in obtaining the history of a case of lipomatous tumor of the knee-joint, may be considered often as a satisfactory cause of its production. This has been well shown in a rather striking case reported by Lauenstein, of Hamburg.[1] This surgeon twice removed tumors of a fatty nature from the knee-joint, and in both instances a marked trauma tism had been received. In one, however, in which the tumor was the size of a plum, and where there had been, three years before, an operation near the articulation for the removal of an enchondrosis, the influence of this injury upon the causation of the fatty movable body in the joint was not clearly apparent; but in the second case the influence of an antecedent accident could be more distinctly made out. It happened in a sailor, aged forty-two, who had sustained, several years prior to his reception into the Seaman's Hospital at Hamburg, a severe compound fracture of the femur at its lower third, which had united with considerable deformity. At a later period a fracture of the patella of the same side had taken place, with rather broad ligamentous junction and decidedly impaired function of the limb. The evening before entering the hospital he had fallen and ruptured, or stretched, the band that held the patella fragments together, and his limb was rendered so useless that wiring of the patella was, after the subsidence of swelling, etc., undertaken. In the performance of this operation it was noticed that the lower part of the joint, from the patellar ligament backward to the crucial ligaments and the *fossa condyloidea*, was filled with a coarse lump of fat, which had (as König had previously suggested) probably been forced through the overlying ligamentum mucosum by the force of the injury which had caused the fracture of the patella a year previously. This mass was removed and the operation completed, with a very tardy but good result. Lauenstein offers the explanation that his first case, where the pedicle arose from the anterior surface of the femur, just above the cartilage, might be classed in those spoken of by König (alluded to above) as due to a gradual accumulation of retro-capsular fat, and that when so occurring it is to be expected that the development of such will be more gradual than those due to the rupture of the subligamentous fat into the joint.

Since treating my last case I have encountered two knee-joints in which I have detected small, movable, soft masses which gave rise to no disturbing symptoms, and which therefore were not subjected to surgical interference. One has been under observation more than a year, without any inconvenience in locomotion. The practical outcome that can be made from the review of so few cases of a somewhat obscure affection is, that too much effort should not be made in the fatty growths to effect their total extirpation, since the removal of the floating portion is all that is called for; and that in the cases where the suspicion of sarcoma is microscopically revealed, the subsequent progress of the two cases observed in the report leads to the belief that the same conclusion will be arrived at.

SARCOMA OF THE CEREBELLUM IN THE CHILD OF A SARCOMATOUS MOTHER.

By GEORGE L. PEABODY, M.D.,

The brain that I have to show you this evening, Mr. President, was removed from the head of a child who died in my service at the New York Hospital. As the interest of the case turns somewhat upon the question of heredity, I will give you the history of the child's mother at some length before proceeding with that of the child.

Mary F——, aged twenty-four, a native of the United States, married, was admitted into the New York Hospital on October 15, 1884. Eight years before, she had noticed a swelling beneath the middle of left side of the inferior maxilla. Three years ago a similar swelling occurred on the right side of her neck. These had grown gradually and without pain. Her general health was excellent at this time.

The tumor on the left side of the neck was as large as a cocoa-nut; that on the right side the size of a small lemon. The skin over them was normal and freely movable. They were smooth in outline, they fluctuated, did not pulsate, and were neither painful nor tender. On aspiration blood only was withdrawn. The tumor on the left side was removed by Dr. W. T. Bull, on October 20th, and that on the right side on November 3d.

Each of these tumors was found to be enclosed in a fibrous capsule, and to consist, besides the blood, whose presence was proved by the aspirator, of rough, shaggy, fleshy masses, growing from the periphery inward toward the centre. This fleshy interior was made up of small, round, and spindle cells in an abundant fibrous stroma. Blood-channels without distinct walls were very numerous, and some of them were large. Many scattered masses of blood-pigment showed that hemorrhages had occurred.

The wound healed kindly, and the woman left the hospital in good condition. These tumors were both fibro-sarcomata.

On December 29, 1885, she was again operated upon by Dr. Bull, and a tumor removed from the left side of the neck, at the site of the growth previously described as removed from that situation. It was about the size and shape of a small hen's egg. It had attracted the patient's attention soon after the previous operation, and had grown steadily. It was almost entirely enclosed in a fibrous capsule, and was very rich in blood, which was found in large vascular channels without distinct walls. It was composed largely of small spindle cells in a fibrous stroma, and was regarded as a spindle-celled sarcoma.

The wound did well, as on the previous occasions, and the patient soon left the hospital in good condition.

A month later she noticed a lump on the left side of her back, between the internal border of the scapula and the spinal column, which in two months had attained the size of a goose-egg. It was hard, smooth in outline, not fluctuating, freely movable, not painful, but slightly tender. The skin over it was normal. This was removed by Dr. Markoe on March 11, 1886. It was found histologically to be in part a fibro-sarcoma and in part a spindle-celled sarcoma. It was not very vascular. The wound did well, and the patient again left the hospital.

On May 6, 1885, she brought her boy, three years of age, to the hospital, and he came under my care. She said that he was always a well child until two weeks before. At that time he began to complain of headache, and became unable to walk, was restless at times, and stupid at others. He had had no convulsions. On admission his temperature was 100°. He was a fairly nourished child. His abdomen was prominent, his chest not very well developed. Here and there over his body were round, pigmented, depressed cicatrices. His pu-

[1] Presented at a meeting

pils were normal in size, and reacted slowly to light. There was slight internal strabismus. He would lie with his extremities all partially flexed much of the time, though often very restless, and making automatic movements with his arms and hands. His head was thrown back, his neck was stiff, the muscles of the neck being very rigid. He took but little notice of what was going on about him, though he decidedly resented interference or examination. His head was large, measuring twenty and a half inches in fronto-occipital circumference. The fontanelles were closed. His respiration and pulse were normal.

On the next day he became quieter, and the rigidity of the muscles of the neck disappeared. When he was placed in a sitting posture his head would fall forward. Ptosis of both eyes began to be developed. His bowels did not move, in spite of a dose of compound licorice powder given on the previous night, and followed by an enema. He began now to suffer from retention. There was no photophobia. After a day or two his bowels were freely moved by castor-oil. Ophthalmoscopic examination revealed a normal fundus in each eye. In a few days double ptosis became more marked, and left facial paralysis was observed. All this time his temperature, respirations, and pulse remained substantially normal, as was also his urine.

After ten days of constant use of the catheter he was given a cystitis and balanitis from which he never recovered. He ate well, but from day to day became more and more stupid. After about two weeks' hospital residence he developed a bronchitis of the larger bronchi. Three weeks after he came under observation he died, on May 27th, having become progressively weaker and more stupid during the previous ten days. A few hours before death he had convulsive twitchings of the hands and feet, but no general convulsions. There was a rise of temperature just before death, ptosis became complete, and the pupils became tightly contracted and not responsive. The post-mortem temperature was 107°.

The autopsy was made six hours after death. The lungs were congested and œdematous. Excepting the brain, now to be described, the other organs were substantially normal.

Brain was well developed. Pons and medulla were both seen to be very much flattened, symmetrically, and the cerebellum unusually prominent. The convolutions were normal. A vertical section through the median line, passing through the cerebellum, cuts into almost exactly equal parts a tumor occupying in the first place the inner two-thirds of the white matter of each lobe of the cerebellum, extending longitudinally from the corpora quadrigemina, along the surface of the medulla, to a point below the decussation of the pyramids, and in width occupying the entire thickness of the cerebellar lobes, a lamina of the superior vermiform process apparently covering the tumor above.

The corpora quadrigemina, which are very much flattened, overlie the anterior upper extremity of the tumor on each side. The tumor seems adherent to the floor of the fourth ventricle throughout, but the substance of the pons and medulla seems to be invaded by the growth only for the depth of a millimetre.

The tumor is in its antero-posterior diameter 6.5 ctm.; its largest vertical diameter is 5 ctm.; its longest transverse diameter is 4 ctm. Its shape is ovoid, the small extremity being forward.

The tumor occupies only the white matter of the cerebellum, its convolutions being apparently free.

The aqueduct of Sylvius and the fourth ventrical seem to be completely obliterated.

The microscope reveals the nature of the growth to be a small round-celled sarcoma of moderate vascularity. I place some sections under the microscope, and you see the characteristic vascular spaces of large size with very thin walls, and some of them without well-defined walls; but the blood-supply is not so great as it frequently is in sarcomata of this class.

The position, size, and general characteristics of the tumor are still well shown in the brain as it lies before you.

The chief interest centres in the occurrence of this tumor of the cerebellum in a child whose mother has repeatedly suffered from sarcomata.

Clinical Department.

A NEW AND ORIGINAL METHOD OF SURGICAL DRESSING.

Dr. Charles W. Strobell, of Middletown Springs, Vt., writes that he was led by the paper of Dr. Hamilton, and the criticisms upon it in recent numbers of The Record, to consider what improvements might be made upon the modes of antiseptic dressing now in use. The main objection to the ordinary dressings of cotton-wool, gauze, etc., is that it conceals the wound from view, so that inflammation, secondary hemorrhage, and other accidents cannot be detected at their onset, and may become only too well established before the surgeon becomes aware of their existence. In order to obviate this, Dr. Strobell proposes to cover the wound with a thin glass globe, so constructed as to fit closely to the part, provided with two openings for drainage-tubes and a large opening on the top to permit of access to the wound, in case of need, without removing the globe. These openings are provided with glass stoppers, so that they can be hermetically closed. The base of the globe is provided with a flange, and its sides, up to within two inches of the drainage-tube openings, are roughened so as to facilitate the adhesion of the isinglass plaster used in sealing it. When applied to stumps after amputation, a thin rubber band, three inches wide, is applied over the flange, so that it rests with one-half its width on the integument of the limb to secure additional safety. The flange is covered on its external surface with isinglass plaster, adhesive on both sides, so that the band of rubber shall adhere firmly to the globe. In the case of an amputation at the knee-joint, after the sutures and drainage-tubes are in place, the wound is capped with a disinfected globe of the proper size to fit snugly over the limb, the drainage-tubes in the globe being on a line with the anterior surface of the wound. The rubber band is now turned down over the limb, and strips of adhesive silk, one inch in width and twelve inches in length, are applied longitudinally from the upper part of the ground portion of the globe up the limb, each strip overlapping slightly the preceding one, a final strip being placed circumferentially around the flange and covering in the ends of the longitudinal ones. In a case of laparotomy an oval-shaped globe may be applied in a similar manner.

The following are the conclusions of the writer: "The method commends itself to the profession: 1. In the complete isolation of wounds that can be obtained in the event of infection of hospital wards by erysipelas, etc., as the globe can be hermetically sealed. 2. All changes can be noted clearly at any moment, with the minimum amount of discomfort to the patient, thereby increasing largely his chances of recovery. 3. The perfection of drainage, which has never been obtained in so great a degree, obviating the necessity of soaking off bandages saturated with dried pus, blood, and serum, often adhering so firmly to the wound that the most gentle manipulation is required to avoid laceration of the tender granulations. 4. Secondary hemorrhage can be detected at the earliest possible moment. 5. The first evidence of inflammation can be noted, and its movement forestalled by removal of the cause. 6. The action of topical remedies can be observed without exposure of

the wound to the air. 7. The dressing can be adapted to wounds of almost every description. 8. Refrigerant and thermal water-dressings can be applied with the utmost facility. 9. Lotions or powders can be easily applied to the wound through the main opening in the globe without disturbing the dressings. 10. If it is desired to prevent the ingress of infected air, the drainage-tubes can be filled with plugs of iodoformed or carbolized cotton. 11. In the event of inflammatory swelling rendering the constriction of the base of the globe excessive, the apparatus can be replaced by one of larger size with less expenditure of labor and time than is required in the application of a Lister dressing. 12. Facility is afforded for determining the therapeutic effect and germicidal action of direct sunlight in the treatment of wounds. 13. By means of long, slender forceps and scissors the sutures, drainage-tubes, and adhesive plaster may be easily removed through the main aperture in the globe. 14. The weight of the apparatus is not as great as that of the ordinary Lister dressing. 15. If perfectly applied, there should be no more constriction of the limb than results from moderately firm bandaging. 16. The expense is comparatively light, as the globes can be used indefinitely, being thoroughly disinfected by boiling water. 17. The apparatus may be adapted to any external surface by taking, in special cases, wax impressions and transmitting them to the manufacturer. In conclusion, I will say that my claim to originality is, in my opinion, well founded, as nowhere in surgical works have I seen glass mentioned, used in the way I have indicated, as a protective dressing."

Progress of Medical Science.

Delusions Caused by Intestinal Accumulations. —Dr. A. E. Bridger relates the following interesting case in the *British Medical Journal* of April 10, 1886. The patient, a lady fifty years of age, had been married twenty-nine years, had brought up a family of six children, and had always enjoyed fair health until about a year ago. At that time she began to lose appetite and flesh; her skin became harsh, dry, and yellowish in tinge; her digestive powers became greatly impaired; once or twice there had been some vomiting of blood, and a troublesome dry cough had developed itself. Remedies failed to relieve her symptoms; and, about eight months ago, mental delusions began to show themselves. These at first took place invariably at night, and were, from first to last, of one class only—namely, that connected with taste and smell. At first, two or three times a week, and of late nightly, the patient would complain that some one was burning sulphur or phosphorus in the room. She became impressed with the idea that her husband and children produced these smells in order to annoy her, and, if possible, to kill her; and twice she had left the house, and remained away for days, in order to rid herself of her supposed persecutors. The smells, however, followed her wherever she went, and she came to believe herself the victim of a widespread conspiracy. About this time she began to refuse food, alleging that it contained poison, and that she could distinctly taste arsenic and sulphur in everything that was prepared for her. When first seen by the writer she was much emaciated, and disinclined to talk, had a stupid and spiritless aspect, a cachectic look of the skin, yellowish conjunctivæ, etc. She made no special complaint, other than of the conduct of her friends. The bowels were said to be regular. The urine was thick, depositing lithates in abundance; no albumen or sugar. Examination of the special senses and of the chest resulted negatively. Inquiries about the abdomen elicited the fact that a sense of weight and of movement had latterly been much complained of, and, on inspection, the position of the transverse and descending colon was seen to be occupied by a large elevated ridge, and the movements of the smaller intestine were distinctly visible through the thin abdominal walls. The elevated ridge was produced by an immense collection of hardened fæces, which it took several days, with the aid of spoon-handles, injections of glycerine, castor-oil, hot water, and the free use of mild aperients, to remove. Within a few weeks after the removal of this accumulation the patient increased greatly in weight, her appetite returned, and she slept easily and quietly. Her delusions disappeared, and her friends stated that she was better, both mentally and physically, than she had been for years.

Herpes Facialis Affecting the Eye. — At a recent meeting of the Ophthalmological Society of the United Kingdom (*British Medical Journal*, April 17, 1886), Mr. W. H. Jessop read a paper based on four cases of herpes facialis affecting the eye. In the first case the herpes followed the track of the external division of the supra-orbital nerve; the eye was affected with iritis, keratitis punctata, and increased tension; recovery, with perfect vision, occurred quickly. In the second, herpes along the lachrymal division of the ophthalmic nerve was followed by keratitis punctata and interstitialis. In the third case there were herpes along the frontal and lachrymal divisions of the ophthalmic nerve, early anæsthesia of the cornea, and superficial keratitis. In the fourth case the herpes followed the course of the infra orbital nerve, and there were phlyctenular ulcers on the cornea. It was pointed out that herpes facialis followed the distribution of the fifth nerve, and that, when the eye was involved, the branch affected was usually the ophthalmic, but sometimes the superior maxillary. The most usual distribution was along the frontal, but there was no recorded instance of the nasal being the only branch affected, nor of the nasal and lachrymal branches being simultaneously attacked, while the frontal escaped. The fourth case was, he believed, the only recorded instance of the cornea being affected in herpes infra-orbitalis. Mr. Hutchinson had pointed out that the eye was affected if the oculo-nasal branch were attacked. The most common ocular complications were swelling of the lids, conjunctivitis, and increased lachrymation; the cornea might become affected by superficial ulceration, phlyctenulæ, interstitial keratitis, or keratitis punctata; and neuroparalytic keratitis had been recorded. Serous or plastic iritis might occur; and the pupil, though generally contracted, had been found sometimes dilated. The chief affection of the fundus was papillitis. The tension was said to be generally lowered. Palsy of the extrinsic muscles and paresis of accommodation had been recorded. After referring to the *post-mortem* evidence of neuritis and dilatation of the ophthalmic artery, Mr. Jessop expressed the opinion that all the ocular symptoms, with the exception of the rarest, might be explained by supposing a dilatation of the vessels due to irritation of the sensory nerve. Vascular dilatation lasting some time would especially influence such a structure as the eye. If the whole attack were due to the neurotic storm, the different nerves would be affected nearly simultaneously, and the ocular symptoms would be coincident with the cutaneous eruption, which was not the case. Mr. Jessop attributed to Mr. Hutchinson the credit of first separating herpes accompanying the ophthalmic division of the fifth nerve from erysipelas.

The Treatment of Menorrhagia. — In young girls, as a rule, a powerful tonic treatment is required. Sometimes the iron is not sufficient, and I have to resort to astringents and tonics not ferruginous. I have used bichloride of mercury and quinine in these cases. Occasionally we meet with cases of this kind in which the patient apparently is in robust health. Under such circumstances I know of nothing better than iodide of potassium.—*Dr. Wm. Goodell.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 26, 1886.

THE QUESTION OF MEDICAL ADVERTISING.

IN order to succeed in the practice of his profession a young physician, or an old one, must not only possess a knowledge of his science and the ability to apply it, but must also make himself known to others, or, as it is usually called, must advertise himself. Great erudition and skill are practically of little value unless they can be made use of to the profit of the possessor or of his fellows. Doctors must have patients, and the problem which all must solve is how to secure patients in order to turn the capital of knowledge into a means of support.

We have received a communication from a valued Iowa correspondent, "E. H. H.," in which the writer advocates newspaper advertising as the surest, most honorable, and best method of securing a profitable clientele. He says:

"Considering the change in the mode of doing business in all trades and professions, there is a possibility that there is some consistency in a demand for some change in ours as well. Specialization in medicine, improved travelling facilities, and the demand on the part of the public for proficiency in all branches of knowledge, change to so great a degree the situation, that a new definition of what constitutes dignity in advertisements seems loudly called for. Advertisement—that word which causes such a bellicose flush to mount into the face of the orthodox—is a word which describes the motive of much of the conduct of a great majority of our brethren in the profession. They must know that to it they owe three-fourths of their success. We must advertise, that is certain. Many are the ways that the physician has to resort to, aside from his 'unintentional' notices in the papers. He spends much of his time at the public resorts—at the corner grocery, at the lodge, church, or saloon—the grade depends upon the social class among which he expects to get his practice, or the town in which he has cast his lot. A higher grade of the methods in advertising is lecturing before schools, exhorting in churches, officiating in lodges, publishing advice, and heading new movements. The founding of the numerous medical colleges figures largely under this head, and may be considered the best of all. If the young physician cannot do these things with sufficient suavity and polish, he will certainly starve on the threshold of his career, or be driven from it to some employment under salary, or to some business that affords an opportunity to make some use of the usual ways of becoming known.

"Is there not, in the relations of the profession of medicine to the public, a necessity which is repugnant and nauseating to a really modest man? Would it not be more dignified to be allowed to announce himself by the methods of a first-class business, under the restrictions above cited, and governed in it by his taste, announcing his business, his place, his facilities, so far as his appliances are concerned, for doing that business? If he has a hospital, let him announce it, leaving out all mention of personal qualifications, advantages had, or relations sustained heretofore; these are the elements that are out of taste and undignified, and the part that should be discountenanced.

"Unwholesome laws which prevent the growth of giants in a profession or trade, but which trim all alike, as a hedge fence, on the ground of fairness toward their neighbors in the same business, dwarf the whole system, and bear fruit below the standard of which the human mind is capable, and prevent a healthy action of that law which determines the fittest man for the work. Every facility consistent with right and true dignity and adaptation to the age should be allowed for development. Life is short, and there is no reason why half of it should be wasted waiting for a living practice only, or that half of it should be given to illegitimate work to make one's self known.

"These arguments, it is true, do not so much apply to the family doctor, or to the attendant on acute diseases and routine practice, as to the practitioner in chronic diseases, who finds himself in circumstances very different. People now are not satisfied with the final judgment of the man who has a general knowledge of the whole round of medical and surgical practice, but seek for the specialist, however distant, to look into their cases, before they are willing to rest their chances for weal or woe. It is easy to learn where to invest money, to get an education, and the safest route to take on a journey; but the same source from which people obtain this information directs them to the lowest level of the representatives of our profession, where they are swindled and get the least skill in the art."

We agree with our correspondent that there is much that is reprehensible in the methods too commonly employed by many physicians to make themselves known and to keep themselves prominently before the public; but we doubt whether the substitute which he proposes would be a desirable one in any sense. A simple and modest advertisement in the public journals would be no guarantee of the advertiser's ability or skill. If all should advertise no one would be more conspicuous than his fellows, and the least conscientious and honorable would be the very ones who would have the most conspicuous and alluring display. The writer applies his remarks more particularly to the specialists; but, whatever may be urged in favor of the general practitioner presenting his claims for patronage in this manner, we cannot admit that the specialist would be justified in so doing. The part of the specialist in medical economy is to assist the general practitioner in cases in which more than the ordinary knowledge and skill is required. It is to the medical profession, and not to the public at large

that the specialist should look for his practice. The family physician has the physical well-being of his patient committed to his trust, and is responsible for its preservation. If he enjoys the confidence of his patient he will naturally be consulted in the selection of a specialist, when necessity may arise, and will recommend the patient to the man whom he considers the most capable and skilful. And surely he would not be influenced in his choice by a well-displayed newspaper advertisement.

We see no objection to a specialist, if he so desire, printing a simple card in the medical journals, but there is another and better way. Let him not only assert his ability to treat certain diseases, but let him prove that he possesses the requisite knowledge by well-written articles. The columns of the medical press are open to all who have anything to say, and who can say it in a way to interest their professional brethren. If a man can show his fellows that he is an expert in his particular field, he will not have to wait long for patients, and he will receive them on the advice, and with the good will, of the family physician. But let him seek, through advertisements in the public press, to draw to himself patients, against the will of their medical advisers, and he is close to the borderland of charlatanism. Honest professional work is what pays best in the long run.

RUMINATION IN MAN.

Among the oddities of medical literature are the accounts which appear from time to time of merycism or rumination in the human being. There are some forty cases of this nature now on record, one of the most recent of which is reported by Johannesen in the *Zeitschrift für klinische Medicin*, vol. x., No. 3. The subject of this relation began to ruminate when he was four years of age, the affection being first noticed during convalescence from measles. About fifteen minutes after a meal a portion of the ingested food was regurgitated, and after this was swallowed another bolus would make its appearance, the process being repeated during a variable period of from ten minutes to an hour. The patient could, by an effort of the will, return the food-mass to the stomach before it had entered the mouth, but all efforts made to prevent the expression of the bolus from the stomach were without effect, and usually caused pain. The man seldom vomited, and never suffered from acid eructations. The matter regurgitated had no unpleasant taste, but, on the contrary, the act of rumination was very agreeable. Œsophageal examination was easy, the sound passing the cardiac orifice with facility, but no diverticula could be discovered in the stomach or œsophagus, nor was there any apparent dilatation of these organs.

In the article on merycism in Jaccoud's "Dictionnaire de Médicine et de Chirurgie," M. Blanchard gives a very interesting account of the affection as he has observed it in his own person, being himself a ruminant. He says that he was always a *mérycole*, and did not imagine that there was anything abnormal about it until he discovered the fact during his studies in physiology. The process is a pleasant one, and the writer confesses to having often selected certain articles of diet in anticipation of the agreeable sensation which he would experience during rumination. If the food have been in the stomach for three or four hours, however, the regurgitated bolus usually has a bitter or sour taste.

The cause of merycism is somewhat obscure. It does not seem to be, strictly speaking, a pathological process, for the subjects of the affection seldom suffer from any unpleasant or painful gastric symptoms. Most of the reported cases have occurred in males, and many of them in large eaters, or else in those who bolt their food without having masticated it thoroughly. The affection may begin at any period of life, but occurs for the most part as a congenital condition, or at least begins so early in life that the subjects do not remember ever to have done otherwise than ruminate. Brown-Séquard suffered for a time from acquired merycism, brought on by certain experiments to determine the period of time required for the digestion of various aliments. He swallowed a sponge attached to a string, in the centre of which the food was contained. After a time he found that his stomach rejected the sponge, and soon it expelled whatever food was swallowed as well. This regurgitation of food continued for a considerable time after the sponge experiments had been abandoned. In most cases, however, no definite cause can be invoked to account for the trouble. In Johannesen's case one of the brothers of the patient was an epileptic, and some other observers have noted a similar relation, if such it be, between epilepsy and rumination.

It would seem probable that merycism should be classed among the neuroses, since in most cases evidence of gastric disease is wanting. The act is probably excited by spasmodic contraction of the muscular coat, assisted by the diaphragm and abdominal muscles, the propulsion upward of the food being favored by a somewhat patent condition of the cardiac orifice. It is not unlikely that the affection may be beneficial, rather than otherwise, to its subjects, since the food, if not subjected to a second mastication and admixture with saliva, might put too great a tax on the stomach, and thus excite gastric troubles.

ON THE AFFECTIONS OF THE JOINTS WHICH COMPLICATE OR FOLLOW SCARLATINA.

An admirable paper bearing the above title was recently read by Dr. Ashby before the Manchester Medical Society. The author traces the literature of the subject through the writings of Trousseau, who admitted the existence of a scarlatinal rheumatism. Bristowe recognized the fact that the joint trouble might go on to suppuration. Dr. Ashby's paper is a summary of our knowledge at present. He makes four classes of scarlatinal joint troubles: first, synovitis; second, acute or chronic pyæmia; third, acute or subacute rheumatism; and fourth, scrofulous disease.

In synovitis he has found the wrists and fingers the most frequent seat of the lesion. Sometimes the tendon sheaths of the flexors and extensors are also involved. The regular symptoms are pain and tenderness, less often redness and swelling. In one case chronic synovitis resulted, lasting sixty days, but the fluid was finally absorbed. The synovial affection generally comes on from the eighth to the tenth day. True rheumatism, however, generally occurs during convalescence, or at

the commencement of the febrile attack. Synovitis is more common in the prolonged cases. Hæmic murmurs are often heard. They are adjudged to be of this nature because of their disappearance during convalescence. From this fact, and from the time of invasion, he claims the possibility of a differential diagnosis between simple synovitis and true rheumatism.

For the synovitis he has prescribed sodium salicylate, more as a matter of routine than from any faith in the drug. He regards the disease as a fugitive one, generally disappearing without any treatment whatever.

It is the septicæmic form which is the most dangerous. Even in cases of recovery permanent cardiac mischief results. The tubercular diathesis naturally determines the nature of a joint complication.

WITCH-HAZEL.

The history of popular domestic remedies for bruises, sprains, and other minor surgical ills is full of interest, and it shows how much a matter of fashion is the mode of treating these complaints. According to Drs. John Marshall and H. C. Wood, in *The Therapeutic Gazette*, thirty years ago the American housewife gathered the flowers of St. John's wort, soaked them in sweet oil, and made with them a so-called "red-oil," for the solace of aching limbs. Later arnica became the universal panacea, while in recent years this has been superseded by various "extracts" of witch-hazel (*Hamamelis virginica*).

Doubtless physicians have often been obliged to listen to stories of the wonderful virtues of this, the mother's latest favorite, and they have perhaps often wondered whether there was any subtle and mysterious element in this plant which evaded the chemist and the pharmacologist, and was only brought out by contact with bruises and black-and-blue spots of all sizes and dimensions. For our text-books, so far as they have spoken, give no reason for witch-hazel being any better application for injured surfaces than arnica, or alcohol, or a dozen other things.

In *The Therapeutic Gazette* for May last, the authors to whom we have referred report the results of experiments made to solve this problem of the popularity of witch-hazel.

A very strong watery distillate of the drug was made, and this was injected in enormous doses into several frogs and into one mammal. The results were absolutely *nil*, and the experimenters conclude that the volatile principle of hamamelis is entirely inert.

Experiments were then made to determine the presence of a volatile oil, and the composition of the alcoholic and ethereal extracts. No tests of physiological properties were made, but the writers state that their conclusions were in harmony with those reached by Dr. Hector Guy, of Paris, who found as a result of numerous experiments that hamamelis virginica is not toxic, that it has no special action on the vascular system, and that it contains no alkaloid. There is a very large percentage of tannic or gallic acid in the fluid extract, and to this and the alcohol it is believed the active properties of hamamelis, such as they are, are due.

The famous witch-hazel preparations, therefore, which cure so many diseases, external and internal, appear to be nothing but dilute tinctures of tannin, made odorous by an inert volatile oil. We fear that there is nothing in the drug which will prevent the fancies of fashion, or the exigencies of trade from overturning its supremacy. Mothers may return to arnica, but more likely some new and wondrous extract will take its place. We shall yet write the history of the decline and fall of witch-hazel.

News of the Week.

Dr. D. Bryson Delavan has been appointed Professor of Laryngology at the New York Policlinic in place of Dr. E. Elsberg deceased.

Dr. Coe's Reply to Mr. Lawson Tait.—Dr. H. C. Coe writes: "Will you kindly allow me a small space in your columns, in order that I may reply briefly to a rather imperious question which Mr. Lawson Tait does me the honor to address to me in your issue of June 19th? He asks for my authority for two quotations which appeared in my recent paper entitled, 'Is Disease of the Uterine Appendages as Frequent as it has been Represented?' I refer him to the original paper (and *not* to a condensed society report), in which he will find the desired information. The second statement, I acknowledge frankly, was made on the authority of Dr. Thomas, as was also stated in the paper. Mr. Tait should not forget that his writings (especially the *polemical* ones) are numerous, and that he may sometimes forget written and verbal statements, which nevertheless carry great weight with the profession at large, especially in America. When he comes to consider my position more calmly, and to remember that the obnoxious paper was read before an American audience, Mr. Tait may find that, so far from seeking to lessen the value of his work in the eyes of my countrymen, I have only insisted upon the very limitations of the so-called 'Tait's operation,' upon which he himself laid such stress in his Edinburgh address."

Conveyance of Infection by Flies and Mosquitoes.—As the warm season sets in, it may be well to be reminded of the fact that Dr. Maddox has published in the *Journal of the Royal Microscopical Society* some experiments on the subject of flies. He fed flies in confinement on the comma bacillus obtained by culture, and found that this organism "can pass through the digestive tube in insects in a living state." Previous experiments by Dr. Grassi, of Rovellasca, point in the same direction. Dr. Manson has proved the conveyance of the ova of filaria sanguinis hominis by mosquitoes, and it has very recently been asserted that yellow fever can be communicated by the same insect.

The Apostle of the Lepers and the Contagiousness of Leprosy.—From the London papers we observe that Father Damen, who has long been known as the Apostle of the Lepers of Molokai, is beginning to suffer from the disease with which he has been so long in contact. For years he has lived on the island upon which are collected the lepers of the Sandwich Island group. For a long time Father Damen continued in good health, but in a letter written recently he says: "Impossible for me to go any more to Honolulu, on ac-

count of the leprosy breaking out on me. The microbes have finally settled themselves in my left leg and my ear, and one eyebrow begins to fall. I expect to have my face soon disfigured. Having no doubt myself of the true character of my disease, I feel calm, resigned, and happier among my people. Almighty God knows what is best for my sanctification, and with that conviction I say daily a good *Fiat voluntas tua*."

The First British Lady Surgeon.—The first lady surgeon qualified in Great Britain was invested with the Letters Testimonial of the Irish College of Surgeons recently, under the new power granted to it by its charter of 1885.

Arsenic in Skin Diseases.—The editor of the *Journal of Cutaneous and Venereal Diseases* is desirous of ascertaining to what extent arsenic is used by American physicians in the treatment of diseases of the skin, and also the results of their experience as to its therapeutical value. Information upon the following points is requested of every physician who reads this: Are you in the habit of employing arsenic, *generally*, in the treatment of skin diseases? In what diseases of the skin have you found arsenic of superior value to other remedies? What ill effects, if any, have you observed from its use? What preparation of the drug do you prefer, and in what doses do you employ it? Address Editor of the *Journal of Cutaneous and Venereal Diseases*, 66 West Fortieth Street, New York.

Successful Porro Operations.—Professor Breisky, of Prague, has performed six Porro operations, and in each case saved both mother and child.

The Sequel of Two Great Operations.—At a recent meeting of the Basle Medical Society, Professor Socin, of Basle, showed the stomach from a woman in whom he had performed, first, resection of the pylorus, and, subsequently, a year later, gastro-enterostomy. The patient died, from return of malignant disease, eighteen months after the second operation.

Of the Dozen Doctors in the English Parliament only four voted with Gladstone for Home Rule.

"The new Medical School at Oxford," says *Truth*, "is hardly a success so far. At the last examination, three learned 'dons' were duly appointed to examine, at a fee of £15 each, but only one candidate presented himself. He was ploughed. People are naturally asking what is the use of paying £1,000 a year to a Professor of Medicine to teach our students nothing."

Medical Exhibition in Berlin.—An exhibition is to be held in September in Berlin, at which it is intended to present a picture of the progress made in recent years in all departments of medical research. The sections will include physiology, pathology, anatomy, and general pathology, pharmacology, dermatology, and syphilology, surgery, gynæcology, ophthalmology, psychiatry, neurology, laryngology, together with military and sanitary affairs. The secretary of the exhibition is Dr. Lassar, 19 Karlstrasse, Berlin.

Seats for the Store-girls.—It is stated that the Board of Health of Chicago has brought a suit against a dry goods firm in that city, for not providing seats for their women clerks.

The Fifty-fourth Annual Meeting of the British Medical Association will be held at Brighton on August 10, 11, 12, and 13, 1886, under the presidency of W. T. Edwards, M.D., F.R.C.S. An address in Medicine will be delivered by Surgeon John S. Billings, M.D., U.S.A. An address in Surgery will be delivered by Frederick Abell Humphry, F.R.C.S. An address in Public Medicine will be given by E. D. Mapother, M.D. The scientific business of the meeting will be conducted in nine sections.

An Industrious Physician.—Professor Balthazar Luchsinger, of Zürich (formely of Berne), who died suddenly, in his thirty-seventh year, in Meran, on January 20, 1886, has left seventy-one original experimental works on physiological, pharmacological, and toxicological subjects; moreover, ten inaugural works were made under his guidance in Berne.

Dr. Edwin J. Bartlett, of Dartmouth College, and Dr. William G. Thompson, of this city, are to lecture on physiology at the University Medical College during the coming session.

The Late Professor Von Gudden was sixty-eight years of age. He left eight children. It is stated that he had nearly one hundred brains, showing various atrophies, which he was intending to study.

Successful Cholecystectomy.—Dr. E. Koehl, of Zürich, describes (in the *Correspondenzbl. für Schw. Aertze*, No. 8, 1886, p. 193) antiseptic cholecystectomy performed by Professor Kroenlein, for dropsy of the gall-bladder, in a woman aged thirty-four. The patient was up and about by the end of the third week, and left the hospital on the forty-first day. When seen five weeks later, she weighed five and a half kilogrammes more than before the operation. It is the eleventh cholecystectomy in literature, according to a correspondent of the *British Medical Journal* (the other ten cases were published by Langenbeck, Heyernam, Reidet, and Courvoisier).

Can Metaphysicians Practise Medicine?—A question is now agitating Chicago medical circles, says *The Sanitary News*, involving the right of metaphysicians to treat disease without submitting to the examination required by the State Board of Health, and possessing the diploma of some reputable medical college. It is needless to state that, were these requirements inflexibly enforced, metaphysicians would be unable to treat patients legally. Dr. John H. Rauch, Secretary of the State Board of Health, thinks the law does not apply to that class of doctors, as they do not treat with medicine and are not, therefore, medical practitioners under the State law. The question will be decided by the State Board of Health at its next meeting.

The Boydston Medical Prize has this year gone to an American, Dr. Charles F. Withington, of Boston, for an essay entitled: "The Relation of Hospitals to Medical Education."

A Homœopath Invited to St. Louis.—It appears that the members of the Medical Press and Library Association of St. Louis conceived and carried out the wicked idea of inviting to the medical editors' banquet the editor of the *N. E. Medical Gazette*, "a monthly journal of homœopathic medicine."

Reports of Societies.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, May 7, 1886.

SAMUEL SEXTON, M.D., CHAIRMAN, *pro tem.*

IN the absence of the author, Dr. R. F. Weir, the paper of the evening (see p. 725), entitled

FATTY AND SARCOMATOUS TUMORS OF THE KNEE-JOINT,

was read by the Secretary, Dr. C. L. Dana.

DR. H. F. WALKER thought that in considering the question of the origin of such tumors it was worth while to mention the fact that the patient whose history Dr. Weir had related, and who had been under Dr. Walker's care at different times, had had the lesions of primary and secondary syphilis, but he had never shown any tertiary manifestations of the disease.

SARCOMA OF THE CEREBELLUM IN THE CHILD OF A SARCOMATOUS MOTHER—CEREBRAL LOCALIZATION—THE SIGNIFICANCE OF THE CHOKED DISK.

DR. GEORGE L. PEABODY presented a specimen of sarcoma of the cerebellum, with a detailed history of the same (see p. 727).

DR. DANA inquired whether any symptoms were produced by the tumor which would throw any light upon localization.

DR. PEABODY replied that pressure upon the corpora quadrigemina and upon the aqueduct of Sylvius, destroying the centre for the third cerebral nerve, would account for the ptosis. It was not evident that any ataxic symptoms were present. When in the hospital the boy was bedridden; there was progressive muscular weakness, but the patient was able to make movements and to resent interference. The mother's account of the case prior to admission to the hospital was not very satisfactory; the boy, she said, had been perfectly well two weeks previously.

DR. AMIDON first saw the patient with him, and they both thought he had tubercular meningitis, but as the case progressed without fever they abandoned this diagnosis. He agreed with Dr. Dana, who remarked that it was singular there was no loss of vision.

DR. ROBINSON asked the gentlemen present whether they had found examination of the fundus of the eye a very important means of diagnosticating brain-tumors. He believed it had been settled by the oculists that it was not.

DR. PEABODY said that in his experience there was usually the so-called choked disk, but not always. In the present case there was none; the fundus of the eye was normal. He was of the impression that the oculists attached greater value to an examination of the fundus of the eye than did general practitioners.

DR. DANA asked what was the origin of the tumor.

DR. PEABODY thought it probable the tumor began near its present centre, in the white matter of the cerebellum, and grew in all directions.

TREPHINING UNDER COCAINE.

DR. C. L. DANA related the following case, the hospital notes having been taken by his house physician, Dr. J. M. Kingman: William H——, single, aged thirty-eight, born in Ireland, a bricklayer, was admitted to the hospital, February 17, 1886. Examination, February 19th: The patient said that his father had had fits. The patient himself had a fit about ten years ago; he fell backward and was unconscious for about twenty minutes. Otherwise he had been a well man until eight months ago. He was then hit on the back of the head by a bar, and remained unconscious for some hours. A day or so later he began to notice difficulty with his speech—a halting and stammering. He also began to notice loss of power in his legs and arms, which has remained about the same. His appetite has remained good; he sleeps well; he has no trouble with micturition or defecation.

Since the receipt of the blow he has had several fits, says he felt dizzy, and had trouble with breathing just before the fits came on. The fits lasted from ten to twenty minutes. He would fall forward and his head would be drawn to one side. The fits recurred once or twice a week. The last one took place four days before admission.

Examination shows left hemiplegia with some atrophy and contractures, the left patella and other tendon reflexes exaggerated. As to skin reflexes—the right cremasteric reflex was exaggerated; left cremasteric reflex abolished; both plantar reflexes good; slight abdominal reflexes on both sides. Sensation for touch and pain good. Left leg and arms somewhat diminished in size. Can move left arm and leg, but cannot walk without support. Arm and leg about equally affected. Face but slightly affected. The patient has considerable halting and lisping in his speech. The mind is weak, memory poor; he cries easily.

On the left side of the head is a deep scar and depression. It is about an inch and a half long, and lies over the left half of the occipital bone.

The urine is pale yellow, alkaline; specific gravity, 1.010; no albumen; clear, with occasional casts; no sediment.

Dr. Dana decided to trephine the patient. The operation was performed by his late house physician, Dr. Symonds. The patient was a rather weak man, and as Dr. Dana had several times seen epileptic patients get an attack under the influence of ether, he thought it proper to try cocaine instead of ether as an anæsthetic in this case. The head was shaved, and about fifteen minims of a four-per-cent. solution of cocaine was injected into the skin in the region of the scar which had been left by the blow.

The injection was made deeply, so as to reach the periosteum. Subsequently other injections were made as needed. After the periosteum had been raised and the trephine applied to the bone, no more cocaine was used, as no pain was complained of. About one drachm of the four-per-cent. solution was employed during the whole operation, which lasted an hour and a half, including the final dressings. At first he employed an incarcerating coil of tubes, applied by the aid of an Esmarch bandage in the way described by Dr. J. W. Wright, but the bandage was so uncomfortable, and finally painful, to the patient, that it had to be removed, and the major part of the operation was performed without any incarcerating coil whatever. The operation, for several reasons, was somewhat prolonged, but the patient endured it without complaint, sitting in a chair with his head resting on his arm on a table in front of him. The incision was made over the occipital bone on the left side, near the junction of the temporal bone, and three inches to the left of the occipital protuberance. A depressed fracture, linear, and over an inch long, was found. The anterior portion showed some loss of bone-substance, which was replaced by fibrous tissue.

A large button of bone was removed, which showed some depression of the internal table. Pieces of bone were also removed with the forceps.

The exposed dura mater did not appear to be sensitive.

After the operation the patient had one fit the next morning and two others a month later. Since then he had remained free from attacks, though taking the same dose of bromide as before (gr. xlv. daily). His mind was much clearer, his speech greatly improved, and he was able to walk alone, when before the attack he could not walk at all, except with the support of attendants.

The speaker said that one interesting feature in the case was the fact that the hemiplegia was on the same side as the injury (the left). It must have been caused, therefore, indirectly by a meningeal hemorrhage, at a point almost diametrically opposite to the point of fracture. A careful examination of the topography of the skull showed that the motor convolutions were in fact directly opposite the depressed fracture. It would, perhaps, have been a rational procedure to have trephined over these convolutions, but the speaker had preferred to attack the visible lesion first.

Dr. Dana spoke of the various methods of mapping out the convolutions on the living head devised by Féré, Championnère, Giacomini, and Reid. They all gave somewhat different results. That of Féré was the one ordinarily used, while that of Reid was the most complete.

Dr. Dana had found in a number of measurements that in American adults the distance from the root of the nose to the coronal suture was 130 to 140 mm. (In an epileptic it was only 120.)

The distance from coronal suture posteriorly, to upper end of fissure of Rolando, was 45 mm. (Féré), 48 mm. (Scwalbe), 53 mm. (Championnère). The distance or dinarily from the root of the nose to the upper end of the fissure of Rolando, therefore, was from seven to seven and three-fourths inches. The fissure passes down and forward from this point to meet a vertical line starting in front of the external auditory meatus, with which line it makes an angle of 30° to 35°.

Dr. Dana showed an instrument cut out of lead, which could be applied to the cranium, and by proper adjustment could be made to show the location of the principal fissures and convolutions. All measurements in the living subject for determining the location of underlying convolutions were only approximate however, and the apparatus exhibited was mainly for assistance in class demonstration.

Dr. Ball asked whether cocaine was employed during the last stage of the operation.

Dr. Dana replied that it was not found necessary after the periosteum had been cut through. They were able to scrape the bone and to rub the dura mater (usually thought to be quite sensitive) without apparently causing the patient any pain.

Dr. J. B. Hunter asked whether there were any definite objections to giving ether, as a rule, to patients subject to epilepsy.

Dr. Dana could reply only by saying that he knew of three instances in which ether had brought on the condition of status epilepticus; two were cases in which he administered the anæsthetic himself. The patients, it was true, came out all right; at the same time he had recently seen a patient die in status epilepticus.

Dr. Hunter had asked the question because he once gave ether to an epileptic patient who became profoundly comatose, and remained so eight or nine hours, notwithstanding efforts to arouse her by artificial respiration, galvanism, etc. While in this state her color was blue.

Dr. R. W. Amidon remarked with regard to cerebral topography that he would be glad if some one would contrive a better method than those now employed for mapping out the convolutions. Those now in use could be readily applied to the denuded skull, but not during life.

The only objection to fixed measurements, like those suggested by Dr. Dana, was the very variable conformation of different heads and consequent variable position of subjacent convolutions. But in ordinary explorations of the head exactness was not demanded, and present methods might answer. He thought it would be worth while for some ambitious young American to repeat and confirm the correctness of Féré's mapping of the convolutions.

The Society adjourned.

OHIO STATE MEDICAL SOCIETY.

Forty-first Annual Session, held at Akron, O., June 2, 3, and 4, 1886.

Wednesday, June 2d—First Day—Afternoon Session.

The President, Dr. William Morrow Beach, of London, called the meeting to order promptly at the appointed hour. Prayer was offered by Rev. R. L. Ganter, and addresses of welcome were made by the Mayor, Hon. L. D. Watters, and Dr. R. E. W. Howard. A fair number of delegates were present at the opening.

The Secretary reported 41 new members, 11 deaths, and 40 forfeitures, making the membership 557, of whom 11 were non-residents. The death-roll was then read, numbering some of the best men of the Society. Suitable notice was made of their decease. Three new societies were reported as applying for the privilege of auxiliaries. Bills amounting to $673.10 were reported.

Vacancies in committees were filled. Reports were made from the Committee on Publication and from delegates to other societies.

Mrs. F. W. Leiter, of Mansfield, made a

temperance speech,

which was well received. A member made a disrespectful reply, which was not well received. Mrs. Leiter is President of the Society for Scientific Temperance Instruction.

miscellaneous business.

A telegram from the Medical Society of Ontario, Canada, was properly responded to.

Dr. H. Z. Gill, of Cleveland, made a verbal report of a "Case of Posterior Torticollis, with Treatment."

Dr. A. Hurd, of Findlay, read a paper on "The Close Relation and Probable Identity between Scarlatina and Diphtheria," which was discussed by Drs. S. B. Hiner, W. J. Scott, James Bennett, L. S. Scovill, H. Z. Gill, W. H. Harmon, and E. Williams.

Dr. N. P. Dandridge, of Cincinnati, read a paper on "The Present Aspect of the Treatment of Vesical Calculus." Discussed by Drs. S. F. Forbes, F. W. Hamilton, and E. W. Russell.

Dr. H. Z. Gill, Chairman of the

committee on the collective investigation of disease,

made the report. He introduced a number of carefully prepared charts showing the relation between the temperature and death-rates, referring especially to Cleveland. During the year there were 518 deaths among children from cholera infantum; 418 occurred during July, August, and September; 375 of them during the two former months; 16 deaths are recorded July 31st; of these 13 were from cholera infantum. The relationship between scarlet fever and diphtheria, as shown by the chart, he thought rather more than accidental. The subject of typhoid fever was also discussed. Ill ventilation, crowding as in sleeping-rooms, school-rooms, etc., he considered great evils. Ventilation dilutes until it destroys; dilution attenuates until it renders innocuous. The reports of Drs. Starling Loveing and C. O. Probst, members of the Committee, were also submitted.

Adjourned for dinner.

Thursday, June 3d—Second Day—Morning Session.

The Committee on Admissions reported a large number of new members. The Committee on a State Board of Examiners Bill reported and were continued. The Committee on Finance reported $340.01 in the treasury. The druggists in session at Springfield were thanked for a kind remembrance by telegraph.

Dr. F. D. Bain, of Kenton, read a paper on

SOME PRACTICAL OBSERVATIONS IN OBSTETRICS.

Discussed by Drs. Merriman, Herrick, Hiner, and A. Dunlap.

Dr. Dudley P. Allen, of Cleveland, reported

A SELECTED CASE OF OVARIOTOMY,

and showed specimens.

Dr. W. B. Hamilton, of Columbus, read a paper on a similar subject.

Dr. B. M. Ricketts read a paper on

EPITHELIOMA, ITS ETIOLOGY, DIAGNOSIS, AND TREATMENT.

He opened with a reference to the extreme amount of suffering entailed upon the subject of cancer. He thought the authorities prone to elaborate and mystify rather than to simplify their thoughts. Owing to the voluminous character of their productions they are to the general practitioner inaccessible. Bichat, Mueller, and Rokitansky first discovered the histological tissue-development. According to Parker, $\frac{1}{150}$th of the deaths of the world are from this disease. On the Nile, among the American Indians, Hindoos, Egyptians, and native negro population of Africa it is absent. It is found most common on the water-courses of England and Wales. Epithelioma is the only form of cancer the origin of which has been satisfactorily associated with previous local disease—constant irritation being the most common cause. It was not till 1840 that Rokitansky placed our knowledge of this disease on a high footing, and epithelioma was known to be a distinct form. It is claimed that the upper lip has an immunity against this disease, but two cases have been reported by Hebra. The average time required to destroy life is fifty-three months, longer than any other form of cancer. The author gave a number of tables going to show that this variety comprises one-fourth of the cases of cancer, that it occurs oftener in men than in women, and that it is found oftenest in the face. The classification of the epithelioma was then discussed. First, the superficial or flat, with which some think the rodent ulcer to be identical, then the deep-seated, then the papillomatous or warty cancer, the most common of them all.

The diseases liable to be confounded with epithelioma are, lupus, syphilis, and rhino-scleroma, from which differential diagnosis is comparatively easy.

Treatment should be both local and constitutional. There is no question but that either form of the disease should be removed as early as diagnosed. The only difference is how to remove it. The superficial is the most easily cured, and is thought by some to be the only one in which caustics should be used. Mr. Erichsen firmly believes that excision with the knife cures. Caustics, though brought into disrepute by charlatans, are undoubtedly of use, The essayist next discussed the actual cautery, the black paste, made of sulphuric acid and saffron, the chloride of zinc paste, caustic arrows, Fells' paste, arsenious acid, Mance's ointment of pyrogallic acid, acetic acid, electrolysis. Escharotics, he said should not be used unless there was a considerable amount of tissue underneath. Cauterants should be followed by warm poultices and carbolized oil dressing. He further discussed repair of the lost parts by flap operations, skin- and sponge-grafting. He recommended highly the local or subcutaneous use of cocaine to relieve pain, spoke of local anæsthesia from salt and ice, but feared sloughing as a result. He recommended, in closing, special attention to the general condition of the patient.

Discussed by Drs. Sisler, Merriman, R. H. Reed, J. T. Whittaker, and William Corlett.

Afternoon Session.

Dr. C. A. L. Reed, of Hamilton, read a paper on

SOME CASES OF ABDOMINAL SECTION.

Three papers having been read on this subject now, it was taken up and a very lively discussion followed. This was taken part in by Drs. A. Dunlap, of Springfield, W. B. Hamilton, of Columbus, and H. J. Herrick, of Cleveland.

THE ELECTION OF OFFICERS

being called for, resulted as follows:

President—Thomas MacEbright, of Akron.
First Vice-President—J. M. Weaver, of Dayton.
Second Vice-President—W. S. Battles, of Shreve.
Third Vice-President—X. C. Scott, of Cleveland.
Fourth Vice-President—Jesse Snodgrass, of Kenton.
Secretary—G. A. Collamore, of Toledo.
Assistant-Secretary—E. C. Brush, of Zanesville.
Treasurer—T. W. Jones, of Columbus.

It was decided to hold the next meeting of the Society in Toledo.

The President, having forgotten his manuscript, did not deliver an address, but read a number of letters from those who could not attend, from home and abroad.

Dr. E. Williams, of Cincinnati, read one of his characteristic humorous papers, full of wit and good hits at quacks and quackery. His subject was "Ocular Delusions." It was greeted with laughter and applause.

Dr. A. B. Threasher, of Cincinnati, read a paper on

HYPERTROPHIC NASAL CATARRH,

in which he thought the disease, as a rule, due to a strumous diathesis in addition to the common irritative causes of chronic nasal catarrh.

There was only difficulty in diagnosis when the hypertrophic tissue has a tendency to become pedunculated, when it may simulate, or really become a true polyp.

The prognosis is wholly governed by the treatment, and is bad if no treatment is instituted. This should be two-fold: constitutional and local. The former should be both hygienic and medicinal, subject to the peculiarities of the case. The local treatment should be the radical removal of the thickened tissue. This should be done, as a rule, by the galvano-cautery.

Friday, June 4th—Third Day—Morning Session.

Dr. R. Harvey Reed, of Mansfield, read a paper—subject,

THE IMPORTANCE OF EARLY OPERATIONS IN SURGICAL INJURIES.

He did not mean rash carelessness, but the sooner a man's limb is off after operation is determined upon the better.

Dr. Dunlap, of Springfield, had been in the habit of operating immediately. He fully endorsed the paper. The A. C. E. was his favorite anæsthetic.

Dr. J. M. Weaver, of Dayton, thought the question when to operate a serious one. It should have our best judgment. The true ground he believed to be the middle, as is the case usually where there are two extremes presented. He doubted if it was good surgery to make the immediate operation when you have a severe accident, as in railroad injury. You had better not operate if there is danger of the patient dying on the table. You had better wait. May be that feeble, flickering life might revive, if not subject just then to another shock.

Dr. E. H. Hyatt, of Delaware, begged leave to take exception to the statement in the paper that the day had gone by when authors advised waiting for reaction. He thought every case to be a rule unto itself. After shock we have a weak heart. Then, will you put a knife to that patient, and add shock to shock? You should know the degree of the shock before operating. If it is not intense, if the patient is suffering from hemorrhage, then operate. What danger is there in waiting if the patient is not bleeding? He favored the use of ether. It is a stimulant, and not so dangerous to the heart. He would not use chloroform, hence not A. C. E., for it contains chloroform. Would not give alcohol. Artificial heat is the best treatment. He wished to enter his pro-

test against the sweeping recommendation, to operate in every case, no matter what the condition of the patient.

Dr. H. Z. Gill, of Cleveland, understood the rule to be, early operation when the case will admit. He thought this settled.

Dr. T. G. Scott, of Cleveland, favored giving Bourbon whiskey.

Dr. R. B. Hall, of Chillicothe, thought the degree of shock should determine whether the operation should proceed or not. He favored dry heat and whiskey.

Dr. N. Gay, of Columbus, thought that ether could be used to diagnose shock. If the patient went down under ether, he should not be operated upon.

Dr. J. W. Hamilton, of Columbus, favored the primary operation below the knee- and shoulder-joint. Above these points, wait. He thought it reasonable to suppose that ether might stimulate reaction, and chloroform retard.

Dr. J. Harmon, of Warren, thought that chloroform as well as ether has a stimulating effect. The apparent depressant effect with chloroform is due to the more rapid anæsthesia. If you push ether to the same anæsthetic effect you will have the same depression. Chloroform as given in obstetrics stimulates.

Dr. N. Gay, of Columbus, read a paper on

THE TREATMENT OF MALIGNANT GROWTH.

He gave the history, treatment, and results, in two cases. Favorite treatment, carbolic acid and olive oil in equal parts.

Dr. Hamilton, of Columbus, thought carbolic acid a two-edged sword. He reported a case where a woman with a felon had applied carbolic acid externally. The finger died and had to be amputated.

Dr. Weaver, of Dayton, reported a case where a young woman came to him with her finger perfectly dead, caused by an application of carbolic acid. It had been applied accidentally and immediately wiped off. Gangrene set in in two or three days.

Dr. Underwood reported the case of a girl, aged ten, who burnt her finger. Her mother having heard that carbolic acid was good for burns, applied it. The finger remained wrapped up till morning when it was found dead; the doctor called, and the finger was amputated.

A lengthy experience-meeting followed, carbolic acid being the subject, drifting into its use for hæmorrhoids.

Dr. J. F. Whittaker, of Cincinnati, read a paper on

THE CARDIAC COMPLICATION OF BRIGHT'S DISEASE.

The essayist commenced by comparing the relation of the heart and kidneys in the machinery of man to that of a force or feeding-pump, and the escape or waste water-pipe. Disease of one was therefore followed sooner or later by disease of the other. In this relation the disease might begin first in the heart and be followed by acute or chronic nephritis; secondly, in both heart and kidneys simultaneously, under the operation of the same cause, as in alcoholism, syphilis, gout, arterio-capillary sclerosis, etc.; and, lastly, in the kidneys, to be followed by pericarditis, much more rarely by endocarditis, but always by hypertrophy of the left ventricle. This hypertrophy, which we now know to be compensatory, hence to be forced and sustained in every way, accompanies every case of chronic nephritis, except in a few cases of extreme debility where new tissue cannot be supplied. It is not limited to renal cirrhosis, but is found equally in chronic parenchymatous nephritis; in fact there is no chronic nephritis without it. It is a valuable sign in that it shows itself early, in the course of from two to four weeks after the reception of the disease in the kidneys, at which time it may be detected chemically as well as demonstrated upon autopsy. The various causes assigned for its production were next discussed, and the symptoms—increased tension of the pulse, dislocation of the apex to the left increased dulness, and accentuation of the aortic tone were dwelt upon in its recognition. The symptoms ar, all the more valuable in that they may all exist in a marked degree in the entire absence of subjective signs on the part of the heart. In the absence of a valve-lesion to account for them they excite the suspicion of the practitioner at once as to the existence of Bright's disease. So long as this compensation is exact there is no dropsy and mostly no uræmia, but so soon as it becomes disturbed with an excess or failure, gross symptoms supervene. Failure is eventually inevitable. It shows itself in the pulse, which becomes weak and quick; next in the lungs with signs of dyspnœa, bronchitis, asthma, and œdema; lastly, in the general system, with anasarca and hydrops of the serous sacs. The paper concluded with the treatment of dilated heart, and urged the importance of gauging the stage of Bright's disease by the condition of the heart.

Dr. H. G. Sharpe, of London, discussed the action of the over-active heart upon the excretions of the kidneys. He thought in weakened heart-action we might have albumen in the urine without kidney trouble.

Dr. William B. Davis, of Cincinnati, reported a case of intermittent albuminuria in an applicant for life insurance.

Dr. Whittaker, in closing, thought albumen in the urine always denotes disease of the kidneys. He thought Dr. Davis' case might be due to malaria.

Dr. Wm. B. Davis, of Cincinnati, read a paper entitled

THE ALCOHOL QUESTION.

He referred to the interests, moral, physical, and temporal, which the question involved. He discussed the physiological action of alcohol in the body. He considered it an antipyretic unless, may be, in the first stage, when the blood is driven to the surface. He thought alcohol was a food. Sulphur is also a fuel. We would hardly use it to heat a room. Alcohol can be used as a food advantageously in fevers and some other diseases, but should not be used in health. He then reviewed the immensity of the subject in this country and in England.

Dr. McIntyre, of Delaware, thought alcohol always deleterious, never beneficial. It is not a stimulant, it is an irritant and a depressor, a narcotic and a poison.

Dr. E. H. Hyatt, of Delaware, discussed alcohol as a food. He was not settled as yet in his belief. One thing controverting this idea is that the power of endurance is not increased.

Dr. W. C. Jacobs read a paper on

PHOSPHOR-NECROSIS.

One of the largest match factories in the United States is in Akron, and consequently the opportunity of observing this disease is quite frequent. He described the process of match-making in detail. About one-seventieth grain of phosphorus is contained in each match-head. In the dipping- and packing-rooms is where the danger of phosphor-necrosis is greatest. Here they are handled more, and in damp weather fumes are given off. The effects of phosphorus are local. In my ten cases all started from unsound teeth. Gums kept from the teeth by tartar is also a cause. It is generally thought that the patient must have been exposed for a long time to the fumes of the phosphorus. Essayist knew one girl who was exposed only two years. The physician rarely sees it in the initial stage. Generally the patient comes a few days after having a painful carious tooth extracted. He wishes to know why he still has pain.

Treatment: Tincture of myrrh is good. Deep incisions have not been so successful in the essayist's hands. He is a firm believer in the early operation. Prevention: First, allow none to work in the dipping and packing department who have not sound teeth; second, good ventilation; third, operators not allowed to eat dinner in their work-rooms, and compelled to keep their hands clean; fourth, keep a solution of the alkaline carbonates near as a mouth-wash.

Dr. F. Garrison, of Mount Vernon, showed a dicephalous monster.

Dr. Sherry, of Tippecanoe, exhibited a case of mastoid trouble, with vomiting and brain symptoms.

Dr. H. J. Herrick, of Cleveland, taking as his subject

DIETETICS IN IDIOPATHIC FEVERS,

presented points which he thought to have been neglected in the treatment of fevers. He referred to dietetics. Too much food is often given. Food not assimilated is a veritable poison. It is my custom to prescribe definitely the food and drink my patients receive. I can bring on malarial fever by means of food. He discussed dietetics with typhoid and bilious fever. Milk, he thought, was sometimes prescribed too freely by physicians in typhoid fever. Give more good pure water.

Dr. J. W. Shively, of Kent, read a paper on

THE EFFECTS OF FOOD IN HEALTH AND DISEASE.

He referred to what food had accomplished in the Colorado beetle by increasing its numbers so greatly. Also how fleet it had made the race-horse, how it had elongated the intestine in the domesticated pig over the wild boar. He discussed food and diet in the treatment of dyspepsia, diarrhœa, scurvy, torpidity of the liver and corpulency. The value of food and diet have been known for a long time. They have not been spoken of highly enough. The value of drugs has been overestimated. We lack the moral courage to say: "You need no drugs, go and do so and so and be whole." We pander to the desire for drugs. We are afraid to give our advice and charge for it, but must give some miserable drugs. The doctor with his drug-store attachment is the most popular.

Dr. William T. Corlett, of Cleveland, read a paper on

DISEASES OF THE SKIN OCCURRING IN THE SUBJECTS OF GOUT.—A REPORT OF THREE CASES.

Case I.—Aged sixty-two, Irish, immediate ancestors free from gout, rheumatism, or any protracted illness. A brother died with symptoms similar to those of this patient. Up till the time of the menopause she enjoyed good health. At this time she suffered from an inflammation of the small joints. At fifty-five an eruption broke out on the legs and finally resulted in two ulcers. The forearms and legs on admission were covered with an eruption of a dark reddish color, slightly scaly, moist only when scratched; itching moderate; joints of foot anchylosed; those of the hand markedly stiffened and enlarged; urine acid at time of passing, specific gravity 1.028, slightly albuminous; serum from a blister treated with acetic acid showed uric acid crystals. Beer and ale disagreed with her since coming to this country, and had been discontinued.

Treatment: Wine colchicum, 10 minims, liq. pot., 10 minims, and inf. gentian, 20 minims, after each meal; ulcers diminished one-half; is now free from eruption.

Case II.—Aged twenty-one, single, daughter of preceding patient. Good health until eighteen, when an eruption appeared on her forearm and legs; very itchy and moist; disappeared and recurred several times. Suffered from muscular rheumatism. She had an eruption which seemed a hybrid between psoriasis and eczema; urine acid at different times, specific gravity 1.018; contained urates, uric acid, and oxalate of lime; saliva acid; serum from blister with acetic acid gave negative results; constipated. She was given blue mass, four grains, and Rochelle salts in hot water before breakfast; tar ointment locally. Recovery rapid.

Case III.—Aged fifty-five, married, Englishman; was a sailor, but obliged to quit on account of scurvy. Then turned painter, and suffered several times from lead colic. At the age of thirty-three, he had a scaly itching eruption, sudden in appearance, which covered the whole body and disappeared soon, but returned with great frequency; complained of general debility and sciatic pains. The epidermis came off in large flakes the size of the palm, the underlying skin being moist; appearance that of advanced senility; anæmic, with marked arcus senilis; muscular tremors and an atheromatous condition of the arteries; urine scanty, twelve ounces per diem, high color, acid in reaction; specific gravity 1.030; albumen, urates, oxalate of lime and granular casts were present; given milk, stale bread and green vegetables *ad libitum*, fresh mutton and beef twice a day with lemon-juice in lieu of coffee or tea, also alkalies, vegetable bitters and Rochelle salts; locally, alkaline baths, followed with tar ointment. Is improving.

Of the lithæmic eruptions which came under the essayist's notice the following are the most noteworthy features: 1, They were scaly; 2, the color was reddish and generally syphilide; 3, there was a tendency to a symmetrical distribution; 4, they were met with in adults, usually after forty-five, except when inherited; 5, they were accompanied by other evidences of lithæmia; 6, they were prone to return. As to diet, cases differ. Some require more than usual, others must be restricted to lenten simplicity. Generally to be interdicted are: Strawberries, rhubarb, apples, pickles, sugar, and acids except in moderation. Eggs, lobsters, and fats are generally badly borne. Malt liquors, port wine, and champagne should be especially prohibited, and the free use of water should be encouraged. Diet, fresh air and exercise. The alkalies, colchicum and the mineral acids are recommended. Rochelle salts, Carlsbad salts or the mineral waters are required at times; again the lithic salts act best, especially if the eruption is accompanied by muscular rheumatism. From colchicum he had derived but little benefit. Local treatment was of little importance, except to mitigate the suffering. The alkaline baths, preparations of tar and ammoniated mercury comprise the means most in vogue and best suited to this end.

Dr. A. W. Ridenour, of Massilon, read a dicephalic paper. First subject: Report on Trephining the Spine; second, The Radical Cure for Hernia. This, in the words of the author, was more of an experience paper than an elaborate scientific affair.

Dr. E. S. McKee, of Cincinnati, read a paper entitled

CONSANGUINITY IN MARRIAGE.

The tenor of the paper was that consanguineous marriages, other things being equal, have no ill effect upon the offspring.

Dr. L. Slusser, of Canton, read a paper on

THE RELATION OF THE PHYSICIAN TO THE PUBLIC.

He did not see why a physician was not as fit for public office as any other class or calling. He referred to the prominence medical men took in the boards of this State during and previous to the time of Governor Chase. Now they are almost entirely absent from these boards. He thought we had disfranchised ourselves by persistently refusing office. The doctor should have a careful watch over the public health. He should constitute himself sanitary inspector of his patient's surroundings. In China, the less sickness there is in a certain district the more pay the doctors of that district receive. He referred to the State Board of Health. It is not all we could wish, yet it is an entering wedge and we should support the board.

Dr. H. Z. Gill presented a resolution of encouragement to the State Board of Health, which was adopted.

Dr. Wm. B. Davis, of Cincinnati, offered amendments to the constitution to the effect that the officers be elected by a committee of one from each county represented, and that the meeting be divided up into sections of medicine and surgery.

The register showed 107 names against 109 last year.

Adjourned to meet at Toledo the third Wednesday in June, 1886.

To the true chronicler of news there remains one fact to relate. Entertainment was absent. The Committee of Arrangements, it seems, had done absolutely nothing. True it is that on this very account one night-session, a very profitable one, was held, the programme cleared, and two volunteer papers read. Nevertheless, to one who had just come from the hospitality of St. Louis, and had, on somewhat similar occasions, been dined and wined at New Orleans and London, there was a want well felt. Akron is not small, and its wealth is great. There exists, apparently, no excuse. This occurred once before in Cleveland, due to a factional quarrel.

Correspondence.

ELECTRICITY IN THE TREATMENT OF EXTRA-UTERINE PREGNANCY.

To the Editor of The Medical Record.

SIR: In his article in THE MEDICAL RECORD of June 12th, Dr. C. C. Lee refers to the use of electricity in extra-uterine pregnancy, and states that it has been popularized chiefly by the writings of Thomas and Garrigues. As no mention of my efforts in this direction was made by Dr. Lee (simply an oversight on his part, I doubt not), it may not be improper for me to say that I have successfully treated eleven well-authenticated cases of this character—an individual experience perhaps unparalleled.

In THE MEDICAL RECORD of February 17, 1883, many of these cases will be found reported, and both in that article, and in the third and fourth edition of "Beard and Rockwell's Medical and Surgical Electricity," I have described more fully than can be found elsewhere the simple details of the operation. One of the unpublished cases I saw very recently in consultation with Drs. Goelet and Lee. It will probably be reported by Dr. Goelet. The twelfth and last case, one of unusual interest and specially instructive, I treated during the past week for Dr. J. E. Janvrin. The full details of the case will soon be given by him. Notwithstanding the number of times that this important therapeutic procedure has been brought to the attention of the profession, the fact still remains that many have incorrect knowledge as to the proper method to be employed; while not a few, strange as it may appear, remain in ignorance even to this day of the fact that in electricity we have a sure and speedy remedy for tubal pregnancy, if detected before the third or fourth month. As a striking illustration of the first statement, reference is made to a series of articles on Electro-Therapeutics, recently published in one of our medical journals, where it was gravely stated, that for the relief of extra-uterine pregnancy a needle is introduced into the sac and electrolysis performed. Comment is unnecessary. The beauty of the operation is its simplicity. No needles are used, the fœtal life being destroyed without danger or special pain to the mother.

A. D. ROCKWELL, M.D.

THE INDISCRIMINATE USE OF ATROPINE.

To the Editor of The Medical Record.

SIR: Your issue of May 29th contains, under "Medical Items," a paragraph referring to a condemnation of the indiscriminate use of atropine for the purpose of dilating the pupil, as an aid to examination, by Dr. Barraquer, in the *Boletin de la Clinica Oftalmologica*. The justice of this reflection upon the frequent use of atropine for this purpose cannot be disputed.

Leaving out of consideration the cases in which atropine is positively harmful, the inconvenience resulting from paralysis of accommodation which atropine induces is often a matter of importance, as in the case of business men and others, who are compelled to distinguish near objects in the discharge of their daily duties.

Were the drug used to paralyze accommodation and thus to aid in determining errors of refraction, such inconvenience would be of secondary consideration; but we find this mydriatic used very frequently, merely to dilate the pupil, for making easy an ophthalmoscopic examination—an aid which the general practitioner makes use of more frequently probably than the ophthalmologist, for the latter's constant practice enables him, in most cases, to explore the fundus oculi through the undilated pupil.

In these cases mydriasis should be produced by *cocaine;* one or two drops of a four-per-cent. solution will dilate the pupil as rapidly as will atropine, the effects will last long enough for even a lengthy ophthalmoscopic examination, accommodation is not as seriously embarrassed, the effects pass off very speedily, and thus there is practically no inconvenience to the patient. Ever since the introduction of cocaine, I have employed it in those cases in which dilatation of the pupil was necessary for ophthalmoscopic examination, and a paralysis of accommodation was not required.

Simple as the substance of the above lines may be, I am led to write them, since, as far as I have observed, the use of cocaine as a mydriatic is still very limited, while it deserves a much more extensive employment for this purpose.

Very truly yours,

CHARLES H. MAY, M.D.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from [illegible] to [illegible], 1886.

FRYER, BLENCOWE E., Major and Surgeon. Sick leave of absence still further extended six months on surgeon's certificate of disability. S. O. 131, A. G. O., June 7, 1886.

TILTON, HENRY R., Major and Surgeon. Ordered for duty Post Surgeon, Presidio of San Francisco, Cal. S. O. 38, Department of California, June 1, 1886.

WATERS, WILLIAM E., Major and Surgeon. Ordered from Department of the East to Department of Columbia. S. O. 133, A. G. O., June 10, 1886.

MERRILL, JAMES C., Captain and Assistant Surgeon. Ordered from Columbus Barracks, Ohio, to Department of Columbia, to take effect upon the expiration of his present leave of absence. S. O. 133, A. G. O., June 10, 1886.

ROBINSON, SAMUEL Q., Captain and Assistant Surgeon. Ordered from Department of Columbia to Department of Texas. S. O. 133, A. G. O., June 10, 1886.

OWEN, WILLIAM O., Jr., First Lieutenant and Assistant Surgeon. Ordered from Department of Columbia to Department of the East. S. O. 133, A. G. O., June 10, 1886.

CARTER, W. F., Captain and Assistant Surgeon. Ordered for duty (temporary) at Fort Concho, Tex. S. O. 55, par. 2, Department of Texas, c. s., granting Assistant Surgeon Carter leave of absence for one month, is revoked. S. O. 64, Department of Texas, June 1, 1886.

BLACK, C. S., First Lieutenant and Assistant Surgeon. Ordered for duty at Fort Stockton, Tex. S. O. 64, Department of Texas, June 1, 1886.

BILLINGS, J. S., Major and Surgeon. Granted two months' leave of absence, with permission to go beyond sea, to take effect July 9, 1886. S. O. 138, A. G. O., June 16, 1886.

LAUDERDALE, J. V., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon at Fort Concho, Tex. S. O. 70, Department of Texas, June 12, 1886.

COMEGYS, EDWARD T., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon at Madison Barracks, Sackett's Harbor, N. Y. S. O. 60, Division of the Atlantic, June 15, 1886.

BLACK, C. S., First Lieutenant and Assistant Surgeon. Ordered from Fort Stockton, Tex., to Fort Clark, Texas. S. O. 69, Department of Texas, June 11, 1886.

Official List of Changes in the Medical Corps of the United States Navy during the week ending June 19, 1886.

SWAN, R., Passed Assistant Surgeon. Detached from the Brooklyn and wait orders.

LOVERING, P. A., Passed Assistant Surgeon. Detached from Navy Yard, New York, and ordered to the Brooklyn.

ARTHUR, GEORGE, Passed Assistant Surgeon. Ordered to Navy Yard, New York.

RUSH, C. W., Passed Assistant Surgeon. Detached from the Franklin and ordered to the Brooklyn.

HAWKE, J. A., Surgeon. Detached from the Wabash and ordered to the Essex, July 1st.

SMITH, HOWARD, Surgeon. Ordered to the Wabash.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 19, 1886:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
June 19, 1886.....	0	9	36	5	65	71	1	0
Deaths.								
June 19, 1886.....	0	2	7	5	3	31	1	0

THE MORTALITY OF DIPHTHERIA.—Dr. Winslow Anderson, of San Francisco, agrees with Dr. Beach in his criticism of the paper on "Diphtheria and its Treatment," as to the mortality statistics there cited. He writes: "To establish the rate of mortality at forty-two per cent. in this much-dreaded disease is open to many objections. In malignant epidemics and endemics of diphtheria which I observed while a resident in Salt Lake City, as well as those seen in San Francisco, I must say, adopt what plan of treatment you may, exclusively local or constitutional, or both, your mortality will not stop at forty-two or fifty-two per cent., but will reach from seventy-five to ninety per cent. On the other hand very mild cases and epidemics occur in which two to five per cent. will cover the death rate. It is well known that not half the cases are reported to the Health Department, so that the statistics are very uncertain. Granting, however, the correctness of the reported cases, every practitioner knows how many pseudo-diphtheritic cases are included—particularly in the so-called "eclectic" and "homœopathic" practice. I do not decry the local treatment, but, on the contrary, use it whenever it is indicated. But of one thing I am very sure, viz., that to hold a little patient as in the case quoted, where the assistant, nurse and father were required to master the little one while the doctor used his spray, is certainly more likely to kill than to cure.

AN INTERESTING RÉSUMÉ OF THE HISTORY OF OVARIOTOMY is given by Lawson Tait. He writes to the *British Medical Journal*: "I have exhaustively studied the history of this operation since its first successful performance by Robert Houston in 1701. Its history may be divided, roughly speaking, into three phases. The first begins with Ephraim McDowell, and ends with Nathan Smith, about the year 1824; and, during these years, the whole achievements of modern surgery were almost equalled in success, if not in extent. The principle of the intraperitoneal treatment of the pedicle with the short ligature was fully established; and the great regret, in the history of the operation, is that it ever was departed from. The second phase begins with Charles Clay, who first performed ovariotomy in England on September 27, 1842; and, during the succeeding twenty-five years, he performed three hundred and ninety ovariotomies, with a mortality of very nearly twenty-five per cent. This second phase ends with the close of the career of Mr. Baker Brown, in 1867. Dr. Charles Clay, unfortunately, departed from the principles of Nathan Smith, and used long ligatures. Baker Brown, on the other hand, adopted a complete intraperitoneal method; and between May, 1865, and September, 1867, he performed forty consecutive operations upon this principle, with a mortality of only ten per cent. The third phase in the history of ovariotomy begins with Mr. Spencer Wells, who, between 1857 and 1878, performed one thousand ovariotomies, with a mortality of twenty-five per cent.; he having, most unfortunately, like his predecessor, Dr. Clay, departed from the successful method of Nathan Smith. This third phase ends with Dr. Thomas Keith, who again re-established Nathan Smith's principle; and from that, I venture to say, no one will ever again have the hardihood to make a deviation."

LADY DOCTORS IN THE FIFTEENTH CENTURY.—Dr. Horowitz, of Frankfort-on-the-Main, has (*The Jewish Chronicle*, May 14, 1884) published a work, entitled "Jüdische Aerzte in Frankfürt," in which the learned author mentions the interesting fact that, as long as four hundred and fifty years ago, Jewesses practised medicine in that city; they especially devoted themselves to ophthalmia. The female oculist, Dr. Zerlin, whom we meet with in the volume as having practised in the year 1428, ventured to reside outside the Judengasse, and believed that she could claim exemption from the payment of taxes on account of her talent, and the general esteem in which she was held. The municipal council rejected her application, and, in 1489, they ordered that Jewish lady doctors should either quit the city or pay taxes like other Jews. A Jewish doctoress was, however, more fortunate in the year 1494; she was relieved from the payment of "sleeping money," a tax imposed on foreign Jews for every day that they stayed in Frankfort. With this exemption was coupled an official recognition of her profession which was of the utmost advantage to the lady.

A CHINESE THEORY OF RABIES.—Dr. George O. Williams, of Greene, N. Y., writes that the Chinese notion of the etiology and treatment of rabies, as given in "La Matière Medicale chez les Chinois," suggests the method of alleged cure, recently mentioned in these columns, as practised by a peasant in Hungary. He thinks the Chinese method may be a traditional antecedent of the treatment mentioned. The following is the account as given in the work referred to: "The 'mylabris cichorii' (the Chinese blistering fly, allied to the cantharis) is frequently prescribed to act upon the urinary organs, and to produce abortion, but it is more highly esteemed as a remedy for hydrophobia. According to the theory which the Chinese hold of that malady, the bite of a rabid dog determines the impregnation of the individual bitten, and a cure cannot be effected until the expulsion of the product of the impregnation is secured through the urinary organs. The hydrophobia persists as long as the gestation continues. Now, as the administration of the mylabris is followed by strangury and sanguineous urine, they suppose the *canine fœtus* to be expelled along with these symptoms."

A German Oculist.—Dr. Duncan writes (in the *Canadian Practitioner*) from Marburg, of Professor Schmidt Rimpler: "His rather tall, well-formed figure, rapid, graceful movements, genial, expressionful eye, with an indescribable air of courage and buoyancy, at once attract and inspire respect. A gentle, quiet manner is almost necessary to success as an oculist, but Schmidt Rimpler has more than that. His thoughtful courtesy toward the poorest and most degraded patient is a lesson to students, teaching them to avoid the harsh, rough, ungentlemanly manner so often assumed by medical men, and reminds one forcibly of the fascinating courtesy toward the lowest of Dr. Gaillard Thomas, of New York, which, as a pattern to the profession, is beyond praise."

Water in the Treatment of Obesity.—M. Albert Robin, arguing that liquids taken in abundance increase the process of oxidation within the economy, lays down the following indications for a liquid or a dry diet in the treatment of obesity. In the case of fat persons who secrete an abnormally large amount of urea, a dry diet should be enjoined. On the other hand, in the case of those whose secretion of urea is below the normal, an abundance of water and other liquids should be prescribed. Finally, when the excretion of urea is neither increased nor diminished, one must look to the "coefficient of oxidation," that is, the relation existing between urea and the solid matters of the urine, for a guide. When the coefficient of oxidation is high a dry diet is indicated, but when it is lowered, fluids should be taken in large quantities.—*Bulletin General de Therapeutique*, April 15, 1886.

The Influence of Forebodings in Disease.—In the *Asclepiad* for January, 1886, Dr. B. W. Richardson writes that there are two kinds of forebodings—the fanciful and the serious. False forebodings are presented by persons of flighty or fanciful natures, who are really fond of contemplating risks, and who suggest anxieties one minute, but laugh at them a few moments afterward. These forebodings have no serious importance. True or serious forebodings emanate from persons who are firm and thoughtful, who, as a rule, keep to themselves what is on their minds until something like a crisis has been reached, when they come to a conclusion to which they adhere and by which they are much influenced. These forebodings in a critical disease are bad: they have a direct effect upon the physical powers, the heart's action is impaired, the digestion becomes affected, and there is a want of tone very much opposed to restorative efforts. It is a wise plan to take as little notice of these forebodings as possible, but to ridicule them is bad.

Tartar on the Teeth.—A correspondent takes umbrage at a paragraph appearing in The Record for April 24th, stating that "some enterprising dentists have named this" (tartar on the teeth) "'Rigg's Disease,' a condition requiring treatment, in place of the old-fashioned scraping off the tartar." Our correspondent thinks this a "slur upon a class of specialists whose work and literature are proof against such defamatory attacks on their own merits. Rigg's disease, or more properly pyorrhœa alveolaris," he says, "is a disease characterized by purulent discharges from the alveolus and occasioning loosening of the teeth and other pathological conditions familiar to dental surgeons. The disease is very common to certain cachexias, notably the scorbutic. Incident to the progress of the disease 'pockets' or recesses are formed between the roots of the teeth and their alveolar investments; in these 'pockets' 'tartar' or 'salivary calculus' *sometimes*, not always, deposits. Tartar *never* is the *only*, seldom an accessory, cause of 'Rigg's disease!'" No surgeon, we believe, could confound suppurative inflammation of the gums with the more familiar accumulations of tartar upon the teeth, but it will scarcely be denied that of the immense number of persons legally entitled to designate themselves "dental surgeon" but few possess the requisite medical knowledge to treat this or any other disease. Our correspondent himself states that the so called Rigg's disease depends on constitutional causes, notably scurvy, a disease which the "class of specialists" called dentists are by no means generally qualified to treat. The Record has already called attention to the fact that a "specialist" capable of treating diseases of the mouth cannot be turned out by a "dental college" any more than a person qualified to practice gynecology could be graduated from a gynecological college. While there are many workmen, both honest and skilful, among dentists, there are but comparatively few physicians among them possessing a medical education and capable of treating such diseases as arise in connection with diseased teeth. That an oral or dental literature exists is due to the labors of medical men rather than dentists. The Record has no wish to disparage the excellent work for which our American dentists are justly famed, but it is to be feared that the too superficial curriculum of the numerous dental schools springing up throughout the country, graduating persons to practise medicine (at least as specialists), will not only contribute to further lower the tone of medical education, but possibly divert attention from the mechanical training every dentist should receive.

Cultivation of Pathogenic Micro-organisms.—Dr. E. Bumm, of Würzburg, advocates, in the *Deutsche Med. Wochensch.*, the use of human blood-serum, adopted by Koch, asserting that it is the only convenient and safe method for producing some specific human micro-organisms. He obtains the serum from the placenta, whence alone he thinks a sufficient supply can be got under ordinary circumstances. He has lately thus cultivated the gonococcus, and, as compared with cultivation with the blood-serum of animals, he finds the results most satisfactory, being able to obtain successive generation. At the very outset, the advantage of the method is apparent in the immediate spreading of the gonococci from the periphery of the pus to the surface of the serum. His method is as follows: He obtains the blood while the placenta is still in the uterus. The umbilical cord having been in the usual way tied and cut, the rest of the cord is cleansed with corrosive sublimate and sterilized water, compressed with the fingers, and again cut above the ligature. The end of the cord is introduced into the neck of a glass retort, the pressure of the fingers is removed, and fifteen to twenty cubic centimetres of blood flow into the vessel at once, and, by waiting for successive pains, forty to sixty cubic centimetres. The blood must be allowed to stand undisturbed for eighteen to twenty-four hours. If proper coagulation follow, fifteen to twenty cubic centimetres of perfectly clear serum may be thus obtained.

Osteo-malacia.—Dr. F. Piesbergen reports six cases of this affection seen in the course of four or five years at the clinic in Tübingen. But one of the cases was sent with the diagnosis previously made, and the writer believes that the disease is more common than is generally supposed, its frequency not being suspected by reason of diagnostic errors. The prognosis, in the earlier stages of the disease, is not wholly bad, and a suitable treatment is often productive of excellent results. It is important to make a careful examination of the pelvis and other parts of the skeleton in women, especially those who have borne many children, who complain of pain in the region of the pelvis, in the lower portion of the spine, and in the inferior extremities, and who experience difficulty in walking or standing. The treatment consists in promoting good nutrition by milk and cod-liver oil. The author places special reliance upon the salts of lime. He gives saccharated carbonate of iron, fifteen grains; carbonate of calcium and phosphate of calcium, each thirty grains; divide into twenty powders, and take one powder twice a day.—*Schmidt's Jahrbücher*, March 15, 1886.

Birth during Hypnosis.—Dr. Edward Pritzl records, in the *Wiener Med. Wochenschrift*, a case of this kind. A young woman was under his care in a lying-in hospital who, he had reason to believe, would be easily brought into a hypnotic condition; and some preliminary trials showed his surmise to be correct. When, therefore, the case ultimately proved to be one in which narcotics should in the usual course be employed, Dr. Pritzl determined to give hypnosis a trial. In spite of her pain and the nervous excitement produced by the presence of several medical men, who wished to witness the experiment, the woman, after looking but a few seconds at the brilliantly-illuminated thermometer-bulb that was passed before her eyes, sunk back, unconscious. The following observations were made: The intervals between the pains lasted nearly two minutes; the pains themselves were more violent than is usual under a narcotic, and lasted on an average fifty seconds, being at their height actively aided by the pressure of the abdominal muscles, and the intensity of the latter was quite normal. The patient was perfectly insensible, but the left lower arm was cramped and the left leg became stiff. There was no change observable in the right side. She turned her head hither and thither as if she were angry, frowned, and groaned. In the intervals, she resembled one asleep. In forty-five minutes from the time she became unconscious, a healthy child was born. In forty-five minutes after this, the woman was roused from her sleep, and would not believe she had been delivered, being hardly willing to own the child. The case, up to the time of writing, had taken a favorable course. Dr. Pritzl lays stress on the following points as remarkable: 1. It was easy to induce hypnosis in such a case as labor. 2. The pains were violent enough to arouse reflex action of the abdominal muscles, but not to rouse the patient. 3. Evidently the hypnotic state accelerated labor, for it had been expected to last several hours. 4. The after-birth stage, which lasted forty-five minutes, was remarkable for the character of the pains, which, though short, were intense and assisted by abdominal action. The loss of blood was slight. Dr. Pritzl has similarly experimented in two other cases, which, though successful, were neither so rapid nor so perfect.

Myrtol.—In a recent thèse de Paris, Dr. Linarix gives an account of the properties of this substance. Myrtol is both an antiseptic and a disinfectant agent. By its presence it prevents the decomposition of fermentative and putrescible organic substances; applied to the skin, it does not produce the slightest irritation, if the epithelium be intact. If there be a slight abrasion, a few drops will produce a very trifling burning sensation, which quickly goes off. Myrtol stimulates the digestive faculties; all who use it find their appetite increased. In small doses it acts as a sedative. It is eliminated by the lungs and kidneys, and has also a powerful balsamic action, but is more easily tolerated than most balsams. Its use is not followed by dyspepsia, nor by any of the other troubles attending the use of balsams in general. Dr. Linarix says that myrtol does not produce the same result at all periods of the affections of the respiratory system; in subacute and chronic catarrhal affections, it should be administered when fever has subsided; then the sputa become less abundant and less purulent. The drug is given in capsules containing each fifteen centigrams (2¼ grains), in doses of two capsules three times a day, before meals.—*British Medical Journal.*

Breathing Cold Air in a Warm Room.—Dr. J. H. Churchill, of Cross River, N. Y., writes: "Seeing a paragraph with this heading in the current number of The Medical Record, I am induced to describe a similar apparatus which I devised about ten years ago. Briefly, it consists of a face-piece of tin, guarded with soft rubber, to cover the mouth and nose, with attachments for two rubber tubes, and fitted with valves so that the air is inspired through one tube, and finds exit through the other. A board three inches wide, and of a length to fit the window in which it is to be used, is pierced with two tin tubes, and to them are attached the rubber tubes. The outer end of each tin tube is protected with wire-strainer cloth to prevent entrance of insects, and also a tin pent-house to guard against rain. The sash being raised the board is placed in the window, and the sash lowered upon it. This device benefits not only the patient, but the attendants also, who are thus relieved from breathing the excreted impurities. After the statement was published of the effect of cold on the tubercle bacillus, it occurred to me that this apparatus could be made efficient the year through by the use of a coil of pipe in broken ice through which the inspired air is drawn. Setting aside theoretical considerations, the practical advantages are, diminished cough (slight temporary increase), improved nutrition, with diminution of night-sweats due to better aëration of the blood, and the by no means unimportant consideration of immunity of the attendants from much that is disagreeable and unwholesome. The apparatus is held in place by a band of elastic webbing around the head, which permits the face-shield to be pushed to one side for the purpose of expectoration. There is one more point of which I have not yet made a practical test, but am about to do so. By arranging a spring so that it can be brought to bear on the outflow valve when wanted, and only when wanted, the effect of breathing into compressed air can be obtained, and a certain amount of expansion of the lung accomplished."

Gastric Syphilis.—Dr. L. Galliard reports some cases of gastric trouble successfully treated with mercury and iodine, and recalls two instances in which Klebs and Cornil found gummy tumors in the wall of the stomach. He concludes that there exists a syphilitic disease of the gastric mucous membrane, which consists in the presence of ulcerated gummata of the wall of this viscus. This gastric syphilis would seem to be less uncommon than has hitherto been supposed, and the author believes that many cases of alleged simple ulcer occurring in syphilitic patients are really referable to the action of the specific virus, and that much good would result from specific treatment in such cases.—*Schmidt's Jahrbücher*, March 15, 1886.

The Treatment of Disorders of the Stomach.—1. *Dyspepsia.*—Causes of Functional Indigestion: (1) Eating too rapidly; (2) drinking too much water at meal-time; (3) improper food; (4) want of exercise; (5) too much tea and coffee; (6) too much tobacco. Treatment: Underdone meats and but little bread. No sweets. Pepsin sacch., gr. v., at each meal. The mineral acids before meals, as muriatic, nitro-muriatic, or phosphoric. Certain bitters, as nux vomica and strychnine combined with gentian or calumba. An alkali a few hours after meals when there is great acidity, but should not be used too frequently.

2. *Dilatation of the Stomach.* — Treatment: Dry, solid food; underdone meats; no milk. Carbolic acid to allay fermentation. Wash out stomach occasionally. Strychnia, hypodermatically or by mouth.

3. *Chronic Gastritis.*—Treatment: Cause to be removed. A scanty supply of food. Pepsin at each meal (gr. v.). Milk, with a little meat, may be taken as food. Oxide of silver, gr. ½, a dose, will be found of value. Bismuth is useful. Avoid tonics, but use the mineral waters to keep portal system drained.

4. *Gastric Pain* (*Gastralgia*).—Treatment: Diet of little importance; stimulus at meals in small amounts. Morphia relieves at once, but use it carefully. (1) Bismuth, with a little opium; (2) nitro-muriatic acid, gtt. ij.–iij., diluted; or, (3) Morph. sulph., gr. $\frac{1}{32}$; acid. carbolici, gt. j.; aq. menth. pip. ad f ℥ j., ter die; (4) Fowler's solution, beginning with gt. j. and increase to gtt. v., ter die.—Dr. Da Costa, in *Coll. and Clin. Record.*

ALEXANDER'S OPERATION ("SHORTENING OF THE ROUND LIGAMENTS").[1]

WITH A REPORT UPON FIFTEEN CASES IN BELLEVUE HOSPITAL.

BY WILLIAM M. POLK, M.D.,

THE remarks indulged in to-night concerning this operation are based upon the results of my labors in Bellevue Hospital.

I have not had sufficient time to study the latest reports from Great Britain, France, or America—the three countries in which the most attention has been paid to it—so that to-night I simply present the outline of my own work, unbiased by that of others. Those who wish to look more deeply into the subject I refer to the little book issued by Mr. Alexander, to the article of Mr. Adams in the *Glasgow Medical Journal*, to an extensive article by M. Doleris, in *Nouvelles Archives d'Obstetrique et de Gynécologie*, No. 1, January 1886, and to the latest one from Mr. Alexander, in the *British Gynecological Journal*, November, 1885.

The situation, origin, attachment, and function of the round ligaments are sufficiently well known to this audience to spare me the necessity of entering into any anatomical or physiological discussion concerning them. There are two points, however, toward which I should direct your attention; these are, their ability to withstand traction, and the effect of the operation upon them and upon the adjacent structures. These ligaments are considered of so little importance, in the non-pregnant state particularly, that we have been in the habit of regarding them as trivial in all respects, certainly as having little capacity to resist anything like prolonged strain.

The observations upon this point made by my colleague, Professor Williston Wright, are, independent of the experience gained by the operations, conclusive. I removed the outer two inches of both ligaments in our case, and handed them to Professor Wright, that he might test their strength by attaching weights to them. This was done, and he reported that one of them broke only when the weight had reached five pounds; the other at four and three-quarters; the portions tested, remember, being the weakest part of the ligaments, the outer ends. By the time that the break occurred they had become stretched to about twice their normal length, but the stretching did not begin until the weight had reached two and three-quarter pounds with one, and three pounds with the other. If, now, we remember how much less than three pounds any prolapsed or retroverted uterus will weigh, it is seen that any part of the ligament is sufficiently strong to answer the objects of the operation. It has been my good fortune to examine and note the position of the uterus, round ligaments, and folds of the broad ligaments in a case which had been operated upon some ten months before, by actually placing my fingers directly upon these parts. It was a case in which the uterus had been held down by a fibroid tumor upon its posterior aspect. The ligaments had been shortened, and the uterus, with its fibroma, was lifted forward and upward, so that the fundus was in the plane of the superior straight. But relief had not been obtained, and the patient, who at the time of Alexander's operation had refused to have Hegar's operation done (removal of the ovaries), now consented to this latter procedure. This offered me an excellent opportunity to observe how far the uterus had maintained its position, as also the condition of affairs about the broad ligaments. The uterus was found to have remained in the position gained for it in the original operation, and the upper border of the broad ligament was spread out like a web, between the round ligament in front, which was moderately taut, and the line occupied by the tube and the infundibulo-pelvic ligament behind, which was also taut. There was no thickening or other pathological condition of these structures. This action upon the upper border of the broad ligament, spreading it out, is what one would naturally expect, and is in miniature what happens, as the uterus, rising in pregnancy, makes taut these same anterior and posterior lines. It was of interest, likewise, to note that the ovaries and tubes were lifted well up, but otherwise were unchanged.

The effect of equal traction upon both of the round ligaments is to lift the fundus of the uterus forward and upward, which movement is in direct proportion to the amount of traction, until the fundus is placed immediately behind the symphysis pubis, where it will stop. If the traction be made upon one ligament only, the fundus will be drawn to one side and upward, until it rests on the pelvic brim, about at the pectineal eminence. In other words, the uterus will follow traction made upon the round ligaments until it is drawn to the anterior and upper parts of the pelvis. Thus, if it be desired to lift the entire organ well upward and forward, as in procidentia, one may rely upon its accomplishment through this traction. And if this be so in these extreme cases of displacement, certainly it will answer in simple posterior displacement, with little or no descent, in which we merely wish to make the organ rotate upon its transverse axis, and perhaps lift it to but a slight degree. These assertions can be verified on either the dead or living body by any competent operator.

I have now and then heard it said that those who have performed the operation upon the cadaver have found some difficulty in drawing the ligaments out from the inguinal canal. I can readily understand this, as it was my own experience in the first dissection made; but I have never had the least trouble in drawing them out on the live subject. I think the difference can be accounted for by the fact that, in the condition of *rigor mortis* (the condition in which such dissections are usually made), the separation of all tissues is more difficult than in the living subject.

A question which at once presents itself is, What would happen should pregnancy occur? Will the uterus be able to rise into the abdominal cavity? This to me was the one possible objection to the operation, until one of my own cases became pregnant, where I have been able to watch the result. The uterus has now completed its sixth month of gestation, and but for a dragging pain along the round ligaments, I have been unable to detect any important deviation from the normal course. The ligaments can be easily felt through the abdominal wall, a rare possibility in pregnancy under other conditions. Mr. Alexander, I believe, has reported several cases that have gone on to term without accident of any kind.

Another question which suggests itself is as to the state of the bladder after the operation. All the cases have been questioned upon this point before leaving the hos-

[1] A paper read before the New York Academy of Medicine, June 17, 1886.

pital, and some several months after. Each one has told me that they suffered no inconvenience with that organ —being able to retain the water as long as usual.

What I have said as to the behavior of the uterus as a result of traction upon the round ligaments, sufficiently explains the *modus operandi* of the operation in relieving the condition to be specified, and the experiments of Professor Wright answer the question as to the ability of these comparatively slender structures to withstand any strain that they might possibly be called upon to bear.

But the crucial test is the clinical result. A number of cases have already been reported by others, and now I beg leave to add fifteen to the list, comprising, as they do, all the patients upon whom I have performed this operation.

Case I.—M. Mc——, aged twenty-three. Uterus retroverted, enlarged, and tender. Suffers from menorrhagia. Has made repeated attempts to wear a pessary, but could not bear the pain it caused. Uterus was curetted, and two weeks later an attempt at Alexander's operation was made. At the expiration of three-quarters of an hour one round ligament had been found, shortened, and stitched in place. The shortening of the second was deferred. The patient expressed so much relief that she was allowed to leave the hospital temporarily, but she did not return. The uterus was drawn to one side and lifted forward, so that it was in the position of latero-version. This operation, though imperfect because of my lack of skill, gave the patient so much relief that she expressed herself as content with the result.

Case II.—J. G——, aged thirty-five. Extreme retroflexion. Cannot wear a pessary. Menstruation irregular and profuse. Bowels constipated, and every movement of them accompanied by pain. Has habitual backache. Operation performed March 16th, 1885. Discharged cured, May 15th. Uterus well up and anteverted.

Case III.—A. M——, aged thirty. This is the case of uterine fibroma mentioned above, in which Hegar's operation was subsequently performed. The result of Alexander's operation was to lift and keep the uterus in a position of anteversion for ten months—in fact up to the date when last seen, which was a year after the original procedure.

Case IV.—A. R——, aged thirty. Uterus retroflexed and left ovary prolapsed. Cannot wear a pessary because of its pressure on the ovary. Suffers constantly from dragging pains in the lower part of the abdomen and the back. Operation performed April 28, 1885. Discharged, cured, June 10th. Uterus anteverted and well up.

Case V.—E. J——, aged thirty. Uterus prolapsed, so that when standing the cervix rests at the ostium vaginæ. It is somewhat enlarged. Suffers from backache and irritability of the bladder. A pessary has been found useless. Operation performed June 17, 1885. Discharged, cured, July 19th. A small sinus remains at the site of the left incision. Uterus drawn well up behind the symphysis, the fundus being about on a level with the superior strait.

Case VI.—A. S——, aged thirty-four. Uterus retroverted, large, tender, and soft. Cervix lacerated, but not ulcerated. She has backache, menorrhagia, and profuse uterine leucorrhœa. A pessary has been tried repeatedly; it caused so much pain it could not be worn. The patient suffers a great deal from nervousness and palpitation of the heart. Operation performed September 21, 1885. The incisions did not heal well, profuse suppuration taking place in both. Slow healing by granulation, therefore, was the result. With this exception she made a good recovery, leaving the hospital with the uterus anteverted and in excellent position, December 7, 1885. She became pregnant about December the 17.

Case VII.—B. C——, aged fifty-one. Fourteen years before entering the hospital prolapse of the uterus occurred as the result of heavy lifting. This has grown steadily worse until the uterus, at the time of this observation, was entirely without the vulva, the vagina being everted. The uterus, even after the patient had been confined to the bed in the hospital for two weeks, measured four inches. The bladder and rectum participated in the prolapse, and as a result there was much annoyance from frequent and difficult urination and painful defecation. Operation performed October 5, 1885. On November 2d following, the wounds had healed, the uterus was well up behind the symphysis, and measured two and a half inches. On November 16th the vagina was narrowed, and the perineum, which had been torn many years before, was repaired. The patient was discharged early on December 26th, cured; the uterus being then in the same position as placed by Alexander's operation, and measuring two and a half inches, as reported above.

Case VIII.—A. S——, aged thirty-eight. Retroversion of the uterus, the organ being bound down by adhesions. Examination showed also tubal disease. Tait's operation was suggested as the surest measure of relief, but it was declined after the pain and tenderness about the uterus had been relieved. Alexander's operation was performed with the hope that we might be able to overcome the traction of the adhesions. The uterus was drawn into the normal position, and the ligaments were stitched to the pubic bone. But in spite of supporting vaginal tampons, the organ lapsed into its former position, so that on leaving the hospital her condition was much the same as it was on admission.

Case IX.—A. R——, aged thirty-five. Uterus retroverted, large and tender, but movable. Has suffered from the displacement for five or six years. Has been under treatment constantly, but never received benefit. Pessaries could never be worn. Operated upon January 25, 1886, the uterus being easily placed in its normal position. Discharged, cured, March 25th. Examined June 20th. The uterus found in its normal position, and the patient stated that she was perfectly well.

Case X.—Aged forty-five. Uterus retroflexed and bound down by adhesions. She suffered a good deal from pain in the back, and the uterus was tender. Menstruation was going on as usual. Operated upon January 9, 1886. The general result was much the same as in Case VIII., although some relief from the troublesome symptoms was obtained.

Case XI.—A. A——, aged thirty. Uterus retroverted, enlarged, and tender, and, as with all the cases except VIII. and X., the organ was freely movable. The usual symptoms of an enlarged and retroverted uterus were present. Had been under treatment for eight years, during which time every device had been tried for her relief, but all failed. Operated upon March 22, 1886. The uterus was placed in excellent position. She had some suppuration in both incisions, which, in connection with rather a depraved state of the general system, retarded the recovery, so that when she was discharged from the hospital, May 15th, her condition was not as good as was hoped for. The uterus was in excellent position. She was seen again June 20th, and then she was better than she had been in years. All the symptoms belonging to the retroversion had disappeared, but a burning pain in the incisions annoyed her a good deal. The uterus was well up and anteverted.

Case XII —B. K——, aged thirty-eight. Uterus retroflexed, enlarged, and tender. She believes that the displacement resulted from a fall five years before admission to the hospital. Has suffered from the symptoms of posterior uterine displacement ever since. Has never been able to get relief, although she has been under treatment for several years. Operated upon April 13, 1886. Discharged, cured, May 17th, the uterus being in good position, anteverted.

Case XIII.—M. C——, aged twenty-three. Both ovaries prolapsed, slightly enlarged, and tender. The uterus, although sharply antéflexed, is very low in the pelvis. She suffers from dragging pelvic pain, has menorrhagia and dysmenorrhœa. These symptoms have been present only one year. Treatment outside of the

hospital has failed to afford relief. Operated upon April 26, 1886, the uterus and ovaries being lifted up and forward, so that they were well away from the posterior pelvic floor, their former position. Discharged May 26th, the uterus and ovaries in the same position as placed by the operation. The troublesome symptoms have disappeared, and she says she is well.

Case XIV.—K. C——, aged twenty-seven. Uterus retroverted, large, tender, but movable. She has suffered for six years from the symptoms of posterior displacement and congestion of the uterus. All treatment has proved unavailing. Operated upon May 28, 1886. Uterus placed in the normal position. The right incision suppurated, otherwise the case did well. June 26th: She is now in the hospital, but is doing so well she will be able to leave in a week or ten days.

Case XV.—A. F——, aged forty-five. Prolapse of the uterus for five years. Operated upon June 23, 1886. The uterus was drawn well up to the symphysis. This is the only case in which I have found the round ligaments fragile. Both of them broke with the ordinary traction before I could draw them from the rings. The canals had then to be opened, the ends were again caught, and by very careful traction I succeeded in getting them well out. The age of the patient would scarcely account for the brittleness, for in Cases VII. and X., the first fifty-one years, the second forty-five, no such condition was found. I can only suggest that possibly it is a condition found in very fat women, for obesity was fully developed in this patient. The ligaments were smaller than in any of the other cases. This patient having been operated upon since my paper was read, too little time has elapsed to make any report upon the result.

A glance at these cases will show that I have applied the operation to all the conditions for which it has been recommended, and to two which have been excluded by the originator of the procedure, the two with adhesions holding the uterus down. The result in these satisfies as to the propriety of excluding all such. So long as the uterus cannot be easily placed in a normal position by the sound, it stands outside the domain of Alexander's operation. Such cases can only be treated successfully by a plan which I have been driven into, namely, by abdominal section; then tearing up the adhesions, and removing the tubes if they require it; but if they do not, by placing a drainage-tube behind the uterus, as we have to do in many ovariotomies, and leaving it in for forty-eight hours. By this method, I believe, we secure permanently an anterior position for the organ.

Recapitulating the conditions for which I have performed Alexander's operation we find them to be: Retroflexions, 4 cases; retroversions, 6 cases; retroversions with prolapsed ovary, 1 case; prolapsed ovaries, 1 case; prolapse of the uterus, 3 cases.

In studying the advantages of Alexander's operation, I confess that its application to cases of prolapse of the uterus has interested me most. At the risk, therefore, of wearying you with a side issue, I will speak more particularly of it. Prolapsus uteri is the joint result of rupture of the perineal structure, and stretching of the uterine ligamentous supports. These supports are chiefly the utero-sacral and basic lines of the broad ligaments. Its principal perineal support is the pubo-coccygeal division of the levator ani, or, as I think it better named, the pubo-perineal division, *enclosed between its layers of fascia.*

The manner of the destruction of the usefulness of this muscle matters but little, the result sooner or later will be the yielding of that portion of the pelvic floor which it guards, and the descent, first, of the vaginal wall, next, of the uterus.

If it were possible in all cases to restore the normal resistance of the pelvic floor we might not find it necessary to do more for the prolapse; but, as a matter of fact, this is rarely accomplished, because of the great difficulty of reaching and uniting the torn ends of the pubo-coccygeal muscle and its fasciæ; or the impossibility of correcting the relaxation due to subinvolution or congenital defect.

That the recognized perineal and vaginal operations fail to reach the essential causes of defect in the pelvic floor is proven by the constant recurrence of prolapse in cases subjected to the most elaborate and thorough operations upon the perineum and vagina. This being so, we must see if aid cannot be obtained from the round ligaments. I am sure that it can be.

It would appear that the prolapse of the uterus is preceded by a backward displacement of it, and there is much reason for believing that if the organ can be kept not only anteverted, but well forward in the pelvis, it will escape the full force of the intra-abdominal pressure and thus avoid prolapse; and again, when prolapse has already taken place, it is natural to suppose that the relaxed ligamentous supports will the more readily regain their normal dimensions and strength if they can be reinforced by some other suspending support. Now by this operation we not only antevert the uterus, but draw it well up and forward, thus giving its ligaments the reinforcement suggested, and if in addition we do what is possible toward the restoration of the pelvic floor, we then will have given the case the best, and, to my mind, the most rational treatment yet devised.

The indications for the operation may now be summed up as follows: Prolapse of the uterus; retroversions and retroflexions of the uterus, in which the organ can be placed in the normal position, and yet a pessary cannot be comfortably worn; prolapse of the ovary, the organ being reducible and not large enough or diseased enough to demand removal.

From this statement it will be seen that the operation has a limited but a well-defined application, and that it reaches cases which, without it, we would either abandon or else subject to graver procedures.

Operation.—I prepare patients for this operation as carefully as I do for an ovariotomy. The bowels are cleared out both by a cathartic and an enema. The food is mainly fluid for thirty-six hours before the patient is placed on the operating-table. Etherization is a necessity. The first step in the operation proper is the shaving of the mons veneris, and then the *thorough* cleansing not only of that space, but the whole of the abdomen and the upper and inner part of the thighs. The vagina should then be carefully washed out with some disinfecting fluid. The entire region is then surrounded with carbolized towels. The operator may now stand between the thighs, which are extended, or else take a position to either side. Next, the guide for the incision is to be sought for, and that is the spine of the pubes. This is to be cut down upon, making the incision parallel to Poupart's ligament, and about two inches or more, if necessary, in extent.

The first objective point is the tendon of the external oblique muscle—for in that lies the external inguinal ring. Having reached it, place a finger on the pubic spine, and slide it upward and outward, about half an inch, then the depression of the ring will be felt. Next clear away all the fat and connective tissue which covers the tendon of the oblique muscle about the ring. In this way it is readily exposed. As you watch it now, you will see a mass of fat and vessels, and sometimes the reddish fibres of the round ligament protruding, and rising and falling with the respiratory movements. This mass should now be seized and drawn out; in a moment the round ligament will come into view; then it should be grasped with the forceps and isolated, continuing the traction it will slide from the ring. If you have mistaken a portion of the tendon of the muscles, you can easily determine the question by running the finger outward along the muscle, for as you make traction you will feel the tendon as a taut line extruding outward above Poupart's ligament. Traction on the round ligament will give no such line. Should you find it necessary to enter the canal in search

of the ligament, in view of the important structures which will be approached, the dissection should be carefully made upon a director.

As soon as one ligament has been isolated, the other should be sought for and isolated in the same manner.

The uterus should now be placed in its normal position, unless the case be one of prolapse of the uterus; then it should be pushed as far up and forward as is compatible with safe pressure.

For this purpose I prefer a sound with as large a bulbous end as can be easily passed into the uterus. The sound is a necessity in cases of retroflexion, but the fingers may be substituted in other cases, being placed either in the vagina or rectum as occasion demands.

The ligaments should now be drawn moderately taut, and stitched to the anterior face of the pubic bone, carefully prepared fine silk being used, three to each ligament sufficing. These, having been cut short, the loose ends of the round ligaments should next be cut away. If the ring gapes, or if you have opened the canal, the columns should be carefully stitched together with silk.

If the incisions have been made through a thick layer of fatty tissue, it is best to introduce bone drainage-tubes, closing the wound around them; but otherwise you may close the wound directly, using deep, silk sutures.

Aseptic cotton tampons are then placed in the vagina, and are allowed to remain for forty-eight hours. I do not know that they are required, but I think it probable that they relieve the strain upon the round ligaments, and thus aid in their secure attachment in the new position. For a month the patient is kept in bed; after that she is allowed to go about at will; but she should be cautioned to avoid straining efforts, for six months at least. Coition should be infrequent for a period of two months, dating from the operation; and this is the more imperative if there be tenderness along the line of the ligaments.

With one patient too frequent indulgence led to a good deal of annoying pain along that line. Mr. Alexander advised, after his early operations, that the patients should wear a pessary for two or three months. I have not found this precaution necessary; all of the patients, so far as I know, having been without them from the date of the operation.

Some operators use but one incision, making it just above and parallel to the crest of the pubes, extending to the outside of each pubic spine. I have not tried this path, consequently I am not in a position to speak of its advantages or disadvantages. I find that an impression prevails to the effect that Alexander's operation is both difficult and dangerous; I cannot say that I have found it so. Any competent surgeon who understands his anatomy, and who is familiar with uterine disorders, can readily perform it, and the dangers are trivial provided the operator is *clean*. Abscesses will develop now and then in the incision, but never if proper precautions are taken, and even when they have occurred with me, no serious result has followed. The question of the development of a cellular inflammation in the broad ligaments, as a consequence of this operation, has also been raised. I can only report that I have had no such result in any of my cases.

Increased experience with the procedure convinces me that it is not a difficult operation, that it is a safe one, and more than all, that it is a valuable addition to the measures of relief which we have to offer to quite a number of weary sufferers.

SMOKING, DRINKING, AND CHEWING.—It is estimated that coca is used by 10,000,000 of the human race; betel-nut by 100,000,000; chicory by 40,000,000; coffee by 100,000,000; 300,000,000 eat, or smoke, hashish; 400,000,000 use opium; 500,000,000 use tea; and all the known people of the earth are addicted to the use of tobacco.

CONSANGUINITY IN MARRIAGE.[1]

BY E. S. McKEE, M.D.,

CINCINNATI, O.

WE find, permeating all classes of all nations, the belief that consanguineous marriages are followed by evil effects upon the offspring. This tradition gains credence from occasional cases where dire results have occurred, and the *post hoc* is taken for the *propter hoc*, the many instances where no evil happened being forgotten.

An endeavor to show the falsity of this belief is the object of this paper.

Attention will be directed, in the greater part, to the marriage of cousins, especially those of the first degree. (This is partially because the majority of consanguineous marriages are between cousins, and because the marriage of relatives nearer than first-cousins, even if proven not to be harmful to the offspring, should be discouraged on other grounds.)

Consanguinity denotes blood relationship. It is quite different from affinity, which signifies relationship by marriage. A man is related to his brother by consanguinity. His wife is related to that brother by affinity.

Lineal consanguinity is that which exists between persons in the direct line of descent or ascent. The consanguinity is collateral when two persons descend from a common ancestor, but not one from the other.

Great confusion has arisen from counting degrees of consanguinity by two different methods. Civil law counts the number of generations up from the one individual to the common ancestor, then down to the other. The canonical law counts the degrees in but one line, the longer, from the common ancestor. The canon law, formulated by Pope Gregory I., A.D. 590–604, is imperfect. It gives persons the same relationship to a certain person when it is not true. Prohibiting marriage in the third degree by the canon law prohibits many more than by the civil law.

The relationship existing between Jupiter and Juno, Osiris and Isis, shows that unions of the closest degrees of consanguinity were not abhorred in ancient mythologies. The story of Œdipus and Jocastra shows that marriage in the direct line of descent was looked upon as impious. The ancient Egyptians intermarried very closely, a large proportion being between brother and sister. The Persians did likewise, as did also the Israelites prior to Moses. Abraham married his half-sister, Sarah; Isaac his first-cousin, Rebekah; and Jacob his two first-cousins, Rachel and Leah. This was a nation renowned for vigor, and in the first fourteen generations reached six hundred thousand fighting men. The sons of Adam must have married their sisters, and we are all descendants from consanguineous marriages, and, according to some, idiots.

The Mosaic law, Leviticus xviii., prohibits the following marriages: With a parent, step-mother, sister, half-sister, granddaughter, aunt or uncle's wife, step-daughter or step-granddaughter, or with a wife's sister during the lifetime of the former.

The Greeks forbade marriage in the direct line of descent, yet permitted it between half-brother and half-sister. The Athenians allowed marriage between brother and sister of the same father, but not of the same mother. The Lacedemonians allowed marriage between uterine brothers and sisters, but not between those having the same father and mother.

The Romans excluded marriage between brothers and sisters, whole or half, and any marriages nearer in degree than first-cousins were practically illegal. The institutes of Justinian forbade marriage in direct line and in collateral line within the fourth degree. First-cousins and all remoter kin might marry.

The present canon law, in force in most Roman Catholic countries, forbids marriage only outside of the fourth

[1] Read before the Ohio State Medical Society, at Akron, June 4, 1886.

degree, that is, third-cousins are forbidden to marry. The civil law allows the fourth civil degree, that is first-cousins, to marry.

Henry VIII. modified very stringent marriage laws in England. They are now practically the Levitical. First-cousins may marry, also nephew and great-aunt, niece and great-uncle. While a man may not marry his grandmother, he may his sister. This law holds in Great Britain, Ireland, and the colonies. The law forbidding a man to marry his deceased wife's sister is not Levitical, and despite the annual effort to throw it off, remains in the home country, but has been dispensed with in Canada and Australia.

The Levitical code is followed generally in the various States of this nation, but New Hampshire, Ohio, and Indiana forbid the marriage of first cousins. Most States forbid a man to marry his aunt or niece, but it is permissible in New York.

Reliable statistics, free from flaws, are exceedingly difficult to procure. The best we can do is to gather all the reliable testimony obtainable.

George H. Darwin, who has so thoroughly studied the marriages between first-cousins in England, says: "It thus appears that in London, comprising all classes, the cousin marriages are about 1½ per cent.; in urban districts, 2 per cent.; in rural districts, 2¼ per cent.; among the landed gentry, 3½ per cent.; aristocracy, 4½ per cent. An average for England of 3 per cent. The average for Scotland is 5½ per cent. This large percentage leads Mr. Darwin to think that such marriages are more frequent in Scotland than in England and Wales. From the mountainous nature of the country this is, perhaps, to be expected. After a thorough search through the institutions for idiots, insane, deaf and dumb, etc., he found that between 3 and 4 per cent. of these descended from consanguineous marriages. In 366 families, in the urban districts other than London, concerning which accurate information could be obtained, 8—that is to say nearly 2.2 per cent.—were the offspring of first-cousins. From his investigations Mr. Darwin had deduced 2 per cent. as the proportion of first-cousin marriages in these districts. Including 350 cases from Newcastle, concerning which the information is not so accurate, reduces this to 1.9 per cent. Probably 3 or 4 per cent. of the patients in the idiot and lunatic asylums are the offspring of first-cousins. Taking into consideration the inaccuracies of the modes of gaining information, both as to the number of these descending from consanguineous marriages and the percentage of these marriages—3 per cent.—the above cannot be said to be in excess. As to deaf-mutes, the proportion of offspring of first-cousin marriages is precisely the same as the proportion of such marriages to the whole number of marriages. Therefore there is no evidence whatever of any ill-results accruing to the offspring from the cousinship of their parents.

Professor Mantagazza, M. Boudin, and Dr. Balley are of the opinion that consanguinity tends to sterility. After a most thorough investigation, making much use of Burke's "Landed Gentry," and "Peerage," Darwin finds that consanguineous marriages are slightly more fertile than the non-consanguineous. He thinks the cause of this is probably the fact that marriages between first-cousins will be more apt to take place where there is a large group of persons who bear that relationship to each other. In such families fertility will be hereditary. The alleged infertility of consanguineous marriages, whether direct or indirect, cannot be substantiated. Mr. Darwin's investigations concerning the alleged excessive death-rate among the offspring of cousins, although rather meagre and unsatisfactory, tend to invalidate the allegation, yet there remains a shade of evidence that the death-rate is slightly higher than among the families of non-consanguineous parents.

Dr. Crichton-Browne, of the West Riding Lunatic Asylum, England, says: "It has always seemed to me that the great danger attending such marriages consists in the intensification of the morbid constitutional tendencies which they favor. Hereditary diseases and cachexia are much more likely to be shared by cousins than by persons who are in no way related, and these are transmitted with more than double intensity when common to both parents. Persons of similar temperaments ought not to marry."

Dr. Howden, of Montrose Lunatic Asylum, Scotland, says: "As regards insanity, my own opinion is, that unless there exists a hereditary predisposition, the marriage of cousins has no effect in producing it. . . . Neither in insanity, nor in any other abnormal propensity, do two plus two produce four; there is always another factor at work, neutralizing intensification and bringing things back to the normal."

Dr. Lauder Lindsay, Murray Royal Institution for the Insane, Perth, Scotland, is of the opinion that the ill effects of cousin marriages are much less, in regard to insanity, than represented.

Dr. Scott, of Exeter, says that 7 out of 241 families in which deaf and dumb children have been born, were first-cousin marriages. In three or four of these families more than one child was so afflicted.

Dr. Arthur Hopper, of the Deaf and Dumb School at Birmingham, out of sixty-two congenitally deaf children, found not one to be the offspring of consanguineous marriages. He thinks it possible for the deafness to show itself in future generations, though dormant now.

Mr. Neill, of the Northern Counties Institution, Newcastle-on-Tyne, says: "350 have been admitted into the institution, and I think in not more than 6 cases were the parents cousins. In one family, whose parents were cousins, there were four deaf-mutes." Mr. Neill has been engaged in the tuition of the deaf and dumb for more than forty years. He thinks the offspring of cousins so affected fewer than supposed.

Mr. David Buxton, of Liverpool, thinks that one in ten of the deaf and dumb in his school descend from consanguineous marriages.

Mr. William Sleight, of the Brighton School, says: "As far as I have been able to ascertain, about seven per cent. of the congenitally deaf children are the offspring of cousins."

Dr. George Wallington Grabham, Asylum for Idiots, Earleswood, says: "Consanguinity of parents accounts (partially only) for about six per cent. of the cases which have been admitted into the asylum during the last six years and a half. In 11 cases only out of 543, the parents were first-cousins, and no other cause could be obtained. Where hereditary predisposition coexists with marriage of consanguinity, we frequently find, as might be expected, more than one child affected. We may, therefore, regard with less disfavor marriages between cousins where there is no hereditary taint on either side."

Dr. Rayner, of the Hanwell Lunatic Asylum, reports 3 out of 255 as the offspring of cousins; Dr. Byewater Ward, of the Warneford, Oxford, Lunatic Asylum, none out of 20; Dr. Adam, Metropolitan District, Caterham, lunatics, 20 out of 560; Dr. Yellowless, Glamorgan County, lunatics, 9 out of 218; Dr. Lawrence, Chester County, lunatics, 3 out of 225; Dr. Mickle, Grove Hall, Bow, 8 out of 181; Dr. Oscar Woods, Hatton, Warwick, 8 out of 258; Dr. Grabham, Earleswood, Surrey, idiots, 53 out of 1,388; Dr. Orange, Broadmoore, lunatics, 2 out of 150; Dr. Gilchrist, Crichton Royal Institution, Dumfries, 4 out of 51; Dr. Anderson, Southern Counties, Dumfries, 8 out of 200; Dr. McIntosh, Perth District, Murthly, 3 out of 78; Mr. W. H. Warwick, Asylum for the Deaf and Dumb, Kent, 52 out of 632.

Dr. Arthur Mitchell, of Edinburgh, Department Commissioner of Lunacy in Scotland, has made a most thorough investigation of the subject in his paper. "Blood Relation in Marriage." (He found among 146 born from 45 consanguineous marriages, 37 of them being fertile, 5.5 per cent. idiots, 3.4 per cent. imbecile, 7.5 per cent. insane, 1.4 per cent. epileptic, 3 per cent. paralytic, 1.4 deaf-

mutes, 2 per cent. blind, 15 per cent. consumptive, scrofulous, or manifestly weak in constitution.) He arrives at the following conclusion: Under favorable conditions of life the apparent ill-effects were frequently almost *nil;* while if the children are underfed, badly housed and clothed, the evil might become very marked. He thinks the danger greater between uterine relatives than those having a common father, but different mothers, for two reasons: one because more good or evil is inherited from the mother; the other because, while we are always the sons of our mothers; yet we may not be the sons of our fathers.

Sir W. Wilde, in his appendix to "Aural Surgery," considers consanguinity of parents as a paramount cause of ear troubles in children.

Mayr found the following proportions of deaf and dumb, out of 10.000 persons, in various countries: in the Netherlands, 6.72; among Netherland Jews, 15.34; in Germany, 19.32; among Bavarian Jews, 36.47; in Baden. 24.24; in Prussia, 12.44.

Reich found deaf and dumb, out of 10,000 persons, as follows: Argentine Republic, 75.74; United States of North America, 8.39; British Australia, 5.65.

He lays this to the fact that in the Argentine Republic the people are enervated and passive. In both other lands they are very active.

In Sweden consanguineous marriages are not more numerous than in North America, yet, from the abuse of alcohol and other habits detrimental to the general system, the frequency of the deaf and dumb is 20.57 to 10,000 inhabitants. Falk also considers the social condition one of the weightiest tendencies to deafness and dumbness.

Boudin and others claim that the greater frequency of mental diseases among earls and the aristocracy is due to consanguineous marriages. It is probable that this is not so much more frequent among them than among other people, but is more noticed. Then, too, why not lay it to debauchery, extravagance, and corruption?

Dr. Charles F. Withington, of Roxbury, Mass., read a paper before the Massachusetts Medical Society in 1885, in which he gave a collection of 108 consanguineous marriages; 103 were fertile, bearing 413 children. Excluding all those having defects of the slightest nature, 312 remained, being 75.5 per cent. This is as high a per centage, certainly, as can be found in any equal number of children taken at random. The defects present could not be ascribed positively to the consanguinity of the parents. They consisted of: Deaf-mutes, 12; insane, 7; idiots, 13; blind, 8; died of consumption, 15; nervous, 5; of less than average intelligence, 8; died in infancy, 16; not robust, 6; hermaphrodite, 1; died of meningitis, 2; cross-eyed, 2; still-born, 2; deaf (not congenital), 2; stammerers, 2; myopic, 2; deformed, 2; epileptic, 1; total, 101.

Of these 108 marriages fertility was present in all save 5. In one of these there was a mechanical impediment on the part of the wife; in another the marriage had lasted only two years. Three of these were physicians, and one a member of the Boston Tea Party, certainly very respectable members of society.

The marriage of Jones and Jones, Brown and Brown, Smith and Smith, probably means the marriage of distant relatives, though the parties themselves are not aware of it.

Dr. Bemis reported to the American Medical Association a collection of 843 consanguineous marriages, producing 3,942 children, 4.6 births per marriage; 28.7 per cent. are put down as defective; 3.6 per cent. as deaf-mutes; 2.1 per cent. as blind; 7 per cent. as idiots; 2.04 per cent. as insane; 1.5 per cent. as epileptic; 7.6 per cent. as scrofulous, and 2.4 per cent. as deformed; 22.4 per cent. are recorded as having died young.

M. Burgeois gives the history of his own family, descended from a consanguineous union in the seventeenth century. Sixty-eight marriages all feel the effects of consanguinity, yet only one was infertile, and this the fault of the wife, a woman of alien stock. The health of all the 200 descendants is excellent, except in one family, where scrofula has crept in.

Seguin gives the particulars of 10 marriages of kin in his own family, two of the number being uncle with niece, and the rest of first-cousins. Sixty-one children were born, not one of whom showed deaf-mutism, hydrocephalus, stammering, or polydactylism. All lived to be grown up.

Dally gives a case of intermarriage between two families, all being first-cousins save two, who were second-cousins. This has continued for five generations, with an average of three or four children per marriage. There has been no case of idiocy or deaf-mutism, and but one of insanity, in an old woman.

M. Voisan reports observations, in the isolated commune of Batz, of 46 consanguineous marriages. These gave 172 children. Sterility occurred in two instances. Mental disorders, idiocy, deaf-mutism, hemeralopia, albinoism, retinitis pigmentosa, or malformations were all unknown. The community consisted of 3,300 souls. They were simple, intelligent, and moral, and had intermarried from time immemorial.

Dr. Cameron makes the statement, based upon the Irish census of 1881, that of the 5,136 deaf-mutes enumerated in the country, 135, or 2.6 per cent. were the children of first-cousins.

Dr. Derby, in a total of 12,130 cases in his ophthalmic practice, has met 23 cases of retinitis pigmentosa. Ten of these were the children of cousins. In none of the 23 cases were any other abnormalities noted. Dr. Derby also gives figures by other observers, which, together with his own just referred to, amount to 210 cases. In 70 there was relationship, in 139 no relationship, in 1 no information.

Dr. Standish, in the Carney Hospital, Boston, in a total of 3,726 patients, found 3 cases of retinitis pigmentosa. In 1 there was no record as to consanguinity, in 1 no relationship, in 1 the parents were first-cousins.

Liebreich found retinitis pigmentosa and deaf-mutism closely connected. From investigations with the ophthalmoscope among the inhabitants of Berlin, he found deaf-mutism among Catholics, who prohibit consanguineous marriages, 1 in 3,000; among Protestants, who permit, 1 in 2,000; among the Jews, who encourage, 1 in 400. According to Liebreich and data from Moorfields Hospital, the development of retinitis pigmentosa is favored by consanguineous marriages.

It will be seen that the testimony is British. Your essayist wrote to a number of British and American gentlemen connected with public institutions, asking for information. The British answered, but the Americans did not. The latter probably did not have the information, or were too busy looking after their political fences to impart it. Your essayist is under many obligations to the gentlemen from England, Scotland, and Ireland.

Conclusions.—1. Like breeds like, good or bad, entirely independent of consanguinity.

2. Evil results have undoubtedly followed consanguineous marriages, but whether dependent upon consanguinity is extremely doubtful.

3. Intemperance, luxury, dissipation, sloth, and shiftlessness, as well as hygienic surroundings and innumerable other causes, among them the depraved moral state dependent on births the result of incest, should bear much of the responsibility laid at the door of consanguinity.

4. Testimony is often weakened by religious or other prejudices.

5. Data are of doubtful reliability, full of flaws and false reasoning. The noted cases are the unfortunate ones. The favorable are unknown or forgotten. It is the ill news which travels fast and far.

6. We as physicians know that there is much more illicit intercourse than is generally discovered. May not

many people be related though not aware of it. Many marriages may thus occur between relatives presumed to be non-relatives, thus again vitiating statistics.

7. Statistics show about the same proportion of deaf-mutes, idiots, and insane persons, descendent from consanguineous marriages, to the whole number of those unfortunates, as the number of consanguineous marriages is to the whole number of marriages. They show fertility among the consanguineous to be slightly greater than among non-consanguineous. They also show a somewhat greater frequency of retinitis pigmentosa.

8. Atavism explains fully the fact that in some instances healthy consanguineous parents beget unhealthy children. This, as is well known, occurs in most hereditary troubles. Furthermore, a less superficial examination may show this healthfulness to be only apparent.

9. Evil results in the offspring of consanguineous marriages prove that *something* was wrong. That it was the consanguinity has not been proven. It may have been one of a hundred things, and dependent on all of the antecedents for generations. Such results remaining absent after these marriages prove, for that case at least, that consanguinity was harmless, for it was known to be present. Further, if consanguinity was the cause, the effect should follow where the cause is present.

10. Consanguineous marriages which bring together persons having a disease or morbid tendency in common are dangerous to the offspring. Not, however, one whit more so than the marriage of any other two persons not related, yet having an equal amount of tendency to disease in common. Conditions present in both parents, good or bad, are simply augmented, and the result would have been the same were they not related.

11. Given, a malformation or disease firmly established, we have a tendency to breed true. Given, a defect or peculiarity in a family, race, or sect, this will naturally be propagated by intermarriage, *e.g.*, color-blindness is remarkably hereditary among the Jews and Quakers. The Quakers are educated to abhor color. Those who admire color separate themselves from the sect and thus intensify the tendency in the remainder. The defect has probably crept among the Jews, and is kept up and intensified by intermarriage. The same means has also had its effect among the Quakers.

12. Certain inherited diseases—as scrofula, phthisis, and rachitis—which are ascribed to consanguineous marriages, probably in every instance, could be traced back to an ancestor.

13. Man is an animal, anatomically, physiologically, and sexually. He is subject to the same laws of propagation. In-and-in breeding in animals is carried on to an extent not only not permissible in the human species, on moral grounds, but also beyond the bounds of human possibility. Yet this is done by cunning breeders to improve the stock and put money into their pockets. The Jersey cattle have been bred for the last hundred and fifty years on a small island, six by eleven miles. You would not raise them for beef or oxen, yet they command a high price for their milk and butter. This was probably the recommendation of the first cattle on the island, and this quality has improved from that time to this through in-and-in-breeding.

14. It would be better for the offspring were consanguineous marriages under medical supervision. Certainly no better than for all marriages to be under like supervision.

15. The half a hundred abnormalities ascribed to consanguinity, including almost all the ills that flesh is heir to—among others, whooping-cough—approaches the ludicrous.

16. The factors which lead to consanguineous marriages are, portions of country geographically isolated or mountainous, rendering communication with the outside world difficult; religious or political sects of an exclusive nature, and aristocratic ideas. As examples, note the percentage of consanguineous marriages in Scotland, 5.25 per cent., to those in England, 3 per cent.; the preponderance in Martha's Vineyard, the commune of Batz, and among the Jews and Quakers.

17. The facts do not warrant us in supposing that there is a specific degenerative effect caused *ipso facto* by consanguinity.

18. Consanguineous marriages, no other objection being present, should not be opposed on physiological grounds.

A New Solvent of Urinary Calculi.—At a recent meeting of the Therapeutical Society, M. Limousin showed a specimen of pichü, or piché. It was a solanum to which the Chilians gave that name. It had recently been introduced into France. In its native country it was believed to disintegrate urinary calculi. M. Limousin prepared a fluid-extract of pichü, of which four dessertspoonfuls represented thirty grammes of the plant, the dose generally administered in twenty-four hours. M. Limousin believed that piché acted especially on the mucin, which held together the different elements of calculi, and dissolved it, and lessened vesical catarrh. In consequence of the resin it contained, M. Dujardin-Beaumetz confirmed this statement.

GENERAL PSORIASIS AND PSORIASIS PALMARIS ET PLANTARIS IN A CHILD.

By GEORGE T. ELLIOT, M.D.,

THE development of psoriasis usually occurs about the age of puberty, or later in adult life, but only in rare instances does it make its appearance in childhood. Dühring mentions a case, seen by Stellwagon, which occurred in a child under five years of age as exceptional, but Kaposi states that he has seen the affection in infants. Without doubt these very early cases present themselves occasionally to every one in large dermatological practice, but they are always viewed with interest as being exceptions to the rule.

That any fundamental reason for this exists does not seem patent to us, since we do not know the cause or causes which produce psoriasis, but as yet are only able to consider the changes in the skin after the disease has developed itself. The changes observed in psoriasis are situated especially in the rete Malpighii, it is true; but whether these changes are primary (Thin, Jamieson, Robinson) or secondary to papillary outgrowth (Vidal, Leloir, Kaposi, etc.), or due to the presence of a parasite (Lang, Wolff, Eslund), or to an inherited weakness of that nervous centre which regulates the nutrition of the skin (Weyl), is as yet entirely undetermined, and even the indisputable proving of either one of the two former views would help in no way in deciding the cause of the affection. The presence of the disease is the only factor of which there is no doubt; but we cannot explain why the affection should appear at times in infants and children, and at others at the age of puberty, and again only after adult life has been reached.

The manifestations of the affection are at all ages similar. With the exception of the palms of the hands and the soles of the feet, which are very rarely implicated in the process, the lesions appear indiscriminately upon all parts of the body, preferring, however, the extensor surfaces of the extremities.

In the following case two points of interest are found: the exceptionally early age at which the psoriasis appeared, and its presence upon both the palms of the hands and the soles of the feet. I have not been able to find in the literature of the subject mention of any case in which true psoriasis plantaris et palmaris occurred at so early an age, though, in all probability, such cases may have been observed.

CASE.—K. K——, female, eighteen months of age, was first seen by me December 28, 1885. She is well nourished, of good size for her age, apparently healthy, though rather pale, but has not yet begun to walk. Her general functions, such as appetite and bowels, are in a normal condition. As far as is known there have been no diseases of the skin in her family. The father and the mother have not, nor have they had, any skin eruptions whatever, and both of their other two children are entirely well. The mother, who came with the child, states that it was in perfectly good health up to the age of thirteen months. It became at that time very peevish, irritable, and restless, and has remained so up to the present. A few days after the inception of this general condition an eruption, consisting of erythematous papules, appeared upon the forehead. These grew larger, slowly becoming covered with thin, whitish brown, easily removable squamæ. The actions of the baby in continually scratching the forehead showed that the lesions were itchy. Succeeding this outbreak similar erythematous papules appeared upon the upper and lower extremities, which in turn were covered with squamæ. No lesions appeared upon the body at all.

Status præsens.—On examining the little patient a diffuse patch was observed upon the forehead extending almost to the eyebrows. Posteriorly it was continued over the vertex as far back as the occiput. The squamæ covering it were easily detached, and from admixture of sebum were slightly fatty. Over the parietal bones were discrete lesions, varying in size from a pea to a nickel, and of typical appearance. Here and there on the face were also a few characteristic lesions. The trunk was absolutely free. On the forearms, about halfway up to the elbows, there were a number of psoriasis lesions varying in size from a pinhead to an ordinary pea.

On the thighs the eruption began at Poupart's ligament, and more or less closely aggregated extended to the knee. On the legs and feet the lesions were quite numerous, and in some places were plaques as large as a twenty-five cent piece. On the labia majora also there were a few spots.

On the palms of the hands four or five small lesions were found. They were about as large as a pea, rosy in color, uninfiltrated, not elevated, and without squamæ. Near the wrist were a few more lesions. On the soles of the feet, both in the arch and anteriorly near the toes, were a number of similar papules. There were seven or eight on each sole, which presented the same characteristics as those on the palms of the hands. The mother stated that these lesions had been present only for a week or ten days.

The baby had been under treatment for a month previously, but the mother said that the eruption had not changed whatever. I gave her minute doses of arsenic in cod-liver oil, and externally applied a three per cent. ointment of hydrargyrum ammoniatum. At the same time good nourishment and frequent baths were ordered.

January 4, 1886.—The eruption had almost completely disappeared from the forehead and head, and had greatly improved upon the rest of the body. She seemed better in every way, less irritable and stronger. Bowels and appetite were in good order.

January 11th.—Only a few of the lesions were remaining. The skin where the lesions had been presented no appearance of redness, but was slightly rough, and slight pigmentation was seen here and there. The spots on the palms and soles were in *statu quo*.

January 20th.—Only two of the lesions have not disappeared. The pigmentation is also less. The palmar and plantar spots are very faint, but still distinguishable.

February 10th.—The baby presents no lesions whatever. The palms and soles are also free beyond a slight rosiness remaining where some of the lesions had been. The general condition of the little patient is greatly improved. She is stronger and is beginning to walk. The same treatment was kept up for a week longer. Since then she has continued getting stronger and better, and has remained free from lesions.

As already pointed out, the age at which the psoriasis appeared in this patient is an exceptionally early one; but aside from this, the presence of the affection upon the palms and soles is important. Not only at an early age, but at every age, the presence of true psoriasis lesions upon these portions of the body is comparatively rare. In fact, so much is this the case that papular lesions, presenting the characteristics associated with psoriasis palmaris et plantaris, if found on these places, are almost invariably set down as being due to syphilis. Some even hold that true psoriasis never appears upon the palms and soles, but if these parts are affected it is unquestionably owing to syphilis. The papular syphilide has a predilection for these portions of the body, it is true, and the condition which has been called psoriasis palmaris et plantaris is seen very commonly in both the early and late stages of this disease; but yet this does not exclude the possibility of non-syphilitic psoriasis occurring there. How often this latter does occur in a given number of cases it is difficult to say. In the last six months I have seen three patients in whom the disease was present at the time of consultation, and one with well-marked general psoriasis, who stated that the affection showed itself first of all on the soles of the feet.

When I saw him, however, these surfaces were entirely free from lesions.

The presence of true psoriasis upon the palms and soles should not offer any particular difficulty in diagnosis. It can be confounded with the early papular syphilide possibly, but that only rarely, since it is very exceptional for psoriasis to be situated on those surfaces alone, but in the same manner as the syphilide it always shows itself more or less distributed over the whole body. Neumann is the only one, I think, who has reported a case in which the true psoriasis was limited to the palms alone, the rest of the body becoming affected only several years later. But it is unfortunate that when psoriasis is present on the palms and soles, many will disregard the lesions present on the body, or consider them as a squamous syphilide, and immediately diagnose syphilis. This was very forcibly brought to my notice last winter by an elderly member of the profession. He had palmar and plantar psoriasis, had been told that it was syphilis, and notwithstandinding the fact that from head to foot he was covered with psoriasis lesions and patches, he had firmly convinced himself that he had syphilis. He had in consequence followed an anti-syphilitic treatment for months, uselessly as might be expected, and was fast becoming hopeless.

It is in such cases that the occurrence of true psoriasis upon the palms and soles must be remembered, and the serious mistake of confounding together two widely different processes be carefully avoided. It is possibly difficult to make a correct diagnosis from the lesions themselves; but yet, in each affection, there are characteristics which, when recognized and given proper weight, go far in leading the practitioner to the proper conclusion. We find that the lesions in true psoriasis appear symmetrically upon both palms or both soles, but in syphilis it very commonly happens that only one palm or sole is affected. Psoriasis appears under the form of erythematous uninfiltrated papules, which offer no subjective symptoms beyond slight itching. In syphilis the papules are of a dark brownish red, presenting a distinct circumscribed infiltration, which is often painful to pressure. In both affections the lesions are only slightly if at at all elevated above the level of the skin.

In psoriasis the papule exists only a short time before squamæ form over it. This does not occur as rapidly as when the lesions are present on the body, owing to the thickness of the epidermis on the palms and soles. The squamæ are rather thick at first, though later offering the same characteristics as do the scales of psoriasis on other portions of the skin, are detachable with ease, and the surface underneath is found to be only slightly infiltrated and bright red in color. The papules may coalesce together, occupying the whole or only part of a palm or sole. In a patient with psoriasis of the palms, who came under my treatment a few weeks ago, the entire palm was implicated, while on the flexor surfaces of the fingers were other lesions, some as large as a nickel, some smaller. In all stages of the papules, from the time that squamæ are first observed, the epidermis scales cover the entire surface implicated, not a portion of it alone, and as long as the affection is present, the renewal of these scales or lamellæ is continuous over this entire surface. The peculiar punctate hemorrhage, seen after removing the scales from a lesion of psoriasis on the body, I have not been able to observe when the disease was present on the palms or soles, nor have I seen a psoriasis annularis or gyrata on these surfaces. Yet even should these latter forms be observed, their characteristics *in toto* would be the same as those already mentioned. Greater care, however, would be called for in giving each symptom its proper weight, owing to the increased possibility of confounding these forms of psoriasis with the late palmar syphilide. Lastly, psoriasis on the palms, like psoriasis on the body, also tends to disappear and to return of its own accord.

In syphilis the papules usually remain intact for three or four weeks, and then desquamation begins. The upper layer of the epidermis, situated over the infiltration, is cast off; a continuous formation of squamæ occurring only at the periphery. At this stage the lesions appear as small scaly rings enclosing a dark brownish-red infiltration covered by a layer of thin epidermis. The lesion may remain presenting this appearance for a variable length of time, and then if treated entirely disappear, or, the infiltration on the centre being absorbed, the scaly rings grow larger peripherally. The formation and renewal of the squamæ are not only different from these same processes in psoriasis, but the scales themselves differ materially in the two affections. Instead of the white, silvery, loosely adherent scales covering the entire lesion, as is seen in psoriasis, we find in the early palmar syphilide small yellowish-white adherent scales, which require some force to remove them, and which are situated around the periphery of the infiltration.

The specific psoriasis palmaris et plantaris does not, however, always appear in the form just described, but at times occurs as very small, sensitive infiltrations, covered with thickened epidermis, which after a longer or shorter time either fall out or can be peeled out like a clavus;[1] or again, under the form of a superficial diffuse infiltration of a brownish-red color, distinctly demarcated and covered by a parchment-like slightly desquamating epidermis. Differentiation between psoriasis and the palmar syphilide which appears in the late stages of syphilis offers no particular difficulty. In this latter the lesions appear in groups or segments of circles. They may become confluent, and then appear as a dense, diffuse infiltration of the skin, covered with thin adherent scales, and bounded by arched borders made up of separate papules; or the lesions may progress peripherally, with consecutive involution, producing the form to which has been given the name serpiginous, one so commonly seen in late syphilis. Fissures are often present, owing to the fact that the dense and deep infiltration yields only with difficulty to the movements of the hands. These, the main characteristics of the palmar and plantar lesions in both psoriasis and syphilis, are thus seen to offer peculiarities which would seem decided enough to exclude errors in diagnosis, and, in fact, if proper signification is given to other lesions which may be present it would be impossible. The differences between them are no less marked when each is treated. Psoriasis of the palms disappears as readily and as rapidly under treatment as psoriasis on other portions of the body, while the persistence and rebelliousness of syphilis on those surfaces is of daily observation.

In the history of the little patient given in this article it was mentioned that there were not any squamæ upon the lesions of the palms and soles. The papules had been present about a week or ten days, and though desquamation was absent yet other characteristic symptoms were not. Even had a doubt existed as to their nature it would have been immediately removed on seeing the typical lesions present on the other portions of the body. Their disappearance under treatment was *pari passu* with those on the extremities, and no factor existed which could have suggested syphilis instead of psoriasis.

[1] For deepest seated.

Carbolic Acid and Chloral.—When carbolic acid and chloral hydrate are mixed together, provided the proportion of carbolic acid does not exceed 1.7 to 1 of chloral, a liquid is formed, as when chloral is triturated with camphor. This liquid is perfectly soluble in water. If more than the above proportion of carbolic acid be present, corresponding to three molecules of carbolic acid to one of chloral, the excess will separate on the addition of water. The substances separate in any case on the addition of heat.

Clinical Department.

TREATMENT OF ASPHYXIA OF THE NEWBORN.

Dr. L. N. Sharp, of Minneapolis, Minn., writes that the perusal of an abstract with the above title in a recent number of The Record, has led him to describe a method accidentally discovered many years ago by himself. He was trying to resuscitate an asphyxiated newborn child, but did not succeed, and the pulsation ceased in the cord. "I cut the cord and continued Marshall Hall's method till I became convinced the child was dead. So many years have now passed that I cannot speak of the condition of the heart, but am under the impression I continued my efforts till the beat of the heart could not be heard. Then I asked for a cloth in which to wrap the body, and took the child in my hands, holding the feet in an elevated position with my right hand, while the back and shoulders of the child, in a depending position, lay upon my left hand. The nurse was tardy in bringing me the cloth, and while I was holding the babe it gasped. I laid it down on the bed and again commenced Marshall Hall's method for resuscitation, but no results; I became convinced again that the child was dead. Taking it in my hands again in the manner above described, I asked for a cloth, and as before had to wait a little, and while waiting the child gasped. The thought came to me at once that the child gasped because the force of gravity carried the blood to the brain, and the lack of this was why the child was dying. I held the child in the same position till gasp after gasp brought respiration and circulation to a normal condition. The child lived. And many, many times since have I resuscitated children which I think would not have lived had I used the ordinary methods."

COCAINE IN LAVAGE OF THE STOMACH.

Dr. Charles N. Dixon Jones, of Brooklyn, writes: "Gastric lavage is rapidly becoming our most reliable treatment in chronic dyspepsia and gastritis. In order to avoid some of the disagreeable features attending this operation, I have resorted to the following expedient: About fifteen minutes before commencing the operation the patient is allowed to hold in his mouth a piece of absorbent cotton saturated with a four per cent. solution of hydrochlorate of cocaine; in a few minutes the palate and fauces are painted with the same solution. The stomach-tube is lubricated with a mixture of olive-oil, oil of wintergreen, and cocaine, after which it may be introduced and the stomach irrigated without that disagreeable vomiting of the tube, and efforts at gagging, which frequently attend the operation. I have adopted this method in some of the most trying and difficult cases, and always with the most happy result."

LARGE DOSES OF IODIDES AND BROMIDES IN MENINGITIS.

Dr. J. F. Stevens, of Shabbona, Ill., reports a case of meningitis occurring in an infant eight months of age. The disease when the child was first seen had so far advanced that parallelism of the eyes was lost, strabismus ensuing. The little patient was evidently failing rapidly, was unconscious, with head retracted somewhat. This condition had come on slowly. There had been no convulsions or convulsive movements. The bowels were extremely constipated, with the abdomen somewhat retracted. The respiration was irregular, and pulse somewhat quickened. A powder containing five grains of calomel was given, and was followed in one hour by a full dose of castor-oil. Blisters were placed behind the ears and mustard to the feet, taking care to cover the soles thoroughly, and an ice-bag was placed at the head. In about one hour the patient aroused somewhat, and in an hour and a half, by which time the bowels moved, cried out several times.

℞. Sodii brom. ..... ℥ ss.
Aquæ,
Syr. simplex ..... āā q.s. ad ℥ iij.
Sig.—One full teaspoonful every hour.

Ten grains of bromide of sodium were given every hour, and one-half grain of iodide of potassium was given every second hour. At the end of twenty-four hours the latter was given only once in three hours. The bromide of sodium was given in doses of gr. x. every hour, continuously, for four days. Under this treatment the condition of the patient slowly improved, but any attempt at reduction of the dose was sure to be followed by bad symptoms.

At the end of four days the bromide was given once in two hours; from this to once in four hours, and then three times a day. The iodide was persisted in until symptoms of iodism manifested themselves, when the medicine was gradually withdrawn. During all this time the ice-cap, filled now with simply cold water, was used. The bowels were kept open with the oil.

Some fourteen days after the case was first seen small abscesses appeared on the scalp, which would discharge about a teaspoonful of pus when opened. These continued until ten were formed. On the eighteenth day the treatment was changed, citrate of iron and ammonium in cod-liver oil three times a day. Small doses of brandy were also given from time to time. The patient is now steadily improving, and bids fair to recover. Both ears have discharged fetid pus freely.

There was no history of syphilitic trouble in the parents, though there had been tuberculosis in a preceding generation.

PERMANGANATE OF POTASSIUM IN AMENORRHŒA.

Dr. F. Tipton, of Selma, Ala., reports a case of amenorrhœa of twelve months' standing, in which all the most reliable emmenagogues, including the faradic current, had been tried without result. The menses reappeared after one week's treatment with the tablets of permanganate of potassium, in doses of two grains, given three times daily, for seven days previous to the expected period.

HYOSCYAMINE IN DELIRIUM TREMENS.

Dr. F. Tipton, of Selma, Ala., has had most satisfactory results with Merck's hyoscyamine, in doses of $\frac{1}{30}$ grain hypodermatically administered, in the treatment of all the distressing symptoms of delirium tremens. He writes: "It has never yet failed me, nor have I experienced any bad results from this drug in these doses. I treat all cases of delirium tremens with this drug as soon as chloral and the bromides fail, and they all get well rapidly. I use the following formula, which I obtained from Dr. P. Bryce, of the Alabama State Insane Asylum: ℞. Hyosciamin, Merck's, gr. j.; alcoholis, ℥ j.; aquæ, ℥ j. M. Sig.—Inject from five to ten minims for one injection."

Centenarians.—The reports which appear from time to time of individuals who have lived to round out a century of existence have frequently been doubted by vital statisticians. In order to settle the question, Professor Humphrey, of England, is now engaged in collecting and sifting these reports, and promises soon to publish those whose authenticity is undoubted.

Progress of Medical Science.

The Differential Diagnosis Between Fibromyomata of the Uterus and Distention of the Fallopian Tubes.—Dr. P. Horrocks, in an article in the *British Medical Journal* of May 1, 1886, thus summarizes the points of difference between these two affections: 1. Fibromyomata are usually accompanied by menorrhagia, and distentions of the tube are not. 2. Fibromyomata, especially when intramural, cause uterine enlargement; while in distention of the fallopian tube the uterus is not enlarged, or only slightly, unless complicated by some other condition. 3. Fibromyomata are usually painless, except that there is often dysmenorrhœa, and, if large, a bearing-down pain, or sense of weight; while in distention of the tube the pain is constant throughout the intermenstrual period, aching in character, and aggravated by the menstrual period. 4. Nutrition is not much affected in fibromyomata, while it is in distention of the tube, especially when the distention is caused by pus; hence, wasting or loss of flesh is a valuable distinction. 5. The temperature is normal in fibromyomata, raised more or less according to nature and amount in distentions of the tube. 6. Fibromyomata, when intramural, move much more rigidly with the uterus than distentions of the fallopian tube. 7. Fibromyomata are much less painful, on pressure, than distentions of the tube. 8. Fibromyomata are usually much firmer in consistence than distentions of the tube. 9. Intermenstrual discharges, usually yellow, are much commoner in distention of the fallopian tube than in fibromyomata. 10. The position and direction of the uterine cavity is much more affected by fibromyomata than by distention of the tube. 11. Fibromyomata are usually more or less spherical, distentions of the fallopian tube cylindrical. 12. Aspiration yields serum or pus in hydrosalpinx or pyosalpinx, and blood in fibromyomata and hæmatosalpinx. 13. Distentions of the fallopian tube are accompanied by pelvic inflammation much more frequently than fibromyomata.

Warm Ether as an Anæsthetic.—Dr. M. W. Hobbs writes in the Cincinnati *Lancet-Clinic* of May 8, 1886, concerning the advantage of warming ether previous to its administration in the production of anæsthesia. He uses a special form of inhaler, in which the ether is warmed by being placed in a chamber surrounded by hot water, and the vapor is mixed with a certain proportion of air before being inhaled. He finds that anæsthesia is produced more rapidly and with the expenditure of less ether, than when the agent is used cold. He and Dr. Taylor have tried the method in upward of thirty cases, and he writes that the patients not only came under the influence of the drug more readily, but they also recovered more rapidly and pleasantly from the anæsthesia than patients generally do who have been brought under its influence in the ordinary way of administering ether cold.

A Clinical Picture of Rachitis.—In an article on this subject, Heubner writes that it is as yet uncertain whether the disease has a premonitory stage. In many cases three classes of symptoms are observed to precede the appearance of the osseous changes: 1. There are certain functional troubles, such as inability to walk, or convulsions, which are the first signs indicating the existence of any morbid process. 2. Chronic digestive troubles or a chronic catarrh of the respiratory passages, following acute infectious diseases, or accompanying chronic infectious maladies, such as tuberculosis. 3. Restlessness, insomnia without appreciable cause, a marked tendency to sweating by night and day, peevishness, and nutritive disturbances, manifested by emaciation and by frequently recurring diarrhœa. These symptoms may present themselves weeks before the apparition of the osseous changes, or they may appear at the same time with the typical rachitic bone lesions, or they may fail altogether. In young children the first change in the osseous system may be sought for in the cranium, the maxilla, the anterior wall of the thorax, and the lower portion of the spinal column. The parts lying in proximity to the two fontanelles and, in general, the parts most recently ossified, are portions of the cranium which are prone to be first attacked. In these regions, soft spots can be felt in the bones, while in those parts which have been longer ossified there is a little hyperplasia and thickening. The first appreciable change is a general pallor, interrupted, on the cheeks, by a faint red tinge. The skin is soft and delicate, and the muscular tissue is modified as regards its volume and firmness. The head loses its rounded form, the occiput is flattened, and there is a depression in the region of the greater fontanelle. The eyebrows are abnormally elevated, and the physiognomy presents an expression of suffering. The thorax projects forward (pigeon breast), the vertebral column is curved posteriorly or laterally, the belly is abnormally large, and the pelvis is flattened; the development of the extremities is arrested, the bones are considerably thickened at the epiphyseal junction, and, in some cases, bent and twisted. The teeth appear late and may be imperfect in their structure; while the vegetative and animal functions of the economy are nearly equal, the intellectual functions may be well developed. In general, the child becomes weak, peevish, apathetic, and apparently suffering all the time. It suffers also from chronic dyspepsia, indigestion, and constipation alternating with diarrhœa. There is also a tendency to catarrhal troubles of the bronchial tubes. The blood participates in the morbid process, as is evidenced by anæmia; there is swelling of the spleen and of the lymphatic glands, and convulsions are frequently observed. The disease is not a local one, limited to one system, but general, involving the entire economy. The older the children the less grave will the disease be, as a rule.—*Journal de Médecine de Bruxelles*, May, 1886.

Congenital Supra-umbilical Fissure.—Dr. Gibert describes, in *La Normandie Médicale* of May 15, 1886, a peculiar condition which he has observed many times, and of which he relates four cases occurring in individuals from the age of three years up to adult life. From a study of these cases he formulates the following conclusions: There is sometimes found in children from the age of three years, and perhaps earlier, a sort of minute eventration, an intermuscular fissure in the linea alba above the umbilicus, forming a buttonhole, which is the cause of a series of accidents which may be briefly stated as follows: Pain in the epigastric region, not constant, which may be very acute, causing the child to utter sharp cries. When the pain is very severe it causes vomiting, usually merely of food. In order to ease the pain the child flexes its body, refusing to straighten up, and sometimes even presses with its two hands on the abdomen, thus indicating very plainly the seat of the pain. The general health is not impaired, and sleep is sound. The symptoms occur only during the day-time, usually while the child is at play. Examination shows the absence of any umbilical or supra-umbilical hernia, and the existence of a supra-umbilical buttonhole or fissure. The writer states that he has never found a loop of intestine engaged in this slit, though such an accident is theoretically possible. As to the mode of formation of this fissure, M. Gibert does not express any decided opinion, though he inclines to the belief that it is due to a congenital absence of fibrous union between the recti abdominales in this situation. The umbilicus is not actually closed until several months after birth, at which period it is occluded at its upper part by a fibrous bundle, containing, as Richet believes, some elastic fibres. It is possible that the continuous crying of the infant during the first weeks or months of life, may weaken this fasciculus at its upper part, and thus open in some way the linea alba between the recti muscles.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 3, 1886.

SUPPRESSION OF PAIN IN LABOR BY THE LOCAL APPLICATION OF COCAINE.

AN American surgeon, Dr. William M. Polk, was the first to make any report regarding the use of cocaine in operations upon the female genital organs. We believe also that an American obstetrician first reported upon the use of cocaine in labor.

This is denied, however, by Dr. M. S. Jeannel, who in an article entitled "The Suppression of Pain in Labor by Local Applications of Cocaine," claims that the idea is essentially French, and was first carried out by MM. Doléris and Dubois. These gentleman, on January 17, 1885, announced that they had applied cocaine locally in eight cases of labor, and in six of them had observed great relief. In September, 1885, Dr. George H. A. Dabbs related his experiences, which were of a similar character, and affirmed that, thanks to cocaine, women could bear children nowadays with very little pain.

Dr. Jeannel (*loc. cit.*) records his observations made during the past year in La Maternité de l'Hôtel Dieu, Saint Eloi. He first applied the cocaine in the form of an ointment with vaseline. He got no results, partly because the vaseline is not absorbed, but mainly, as he believes, because corrosive sublimate injections were made, which drug decomposes the cocaine—a fact worthy to be borne in mind. Aqueous solutions were then employed, and it was found that a five per cent. solution was sufficiently strong. In the first stage of labor a speculum was used, and the solution painted over the neck and vagina, or a tampon, saturated with the solution, may be introduced. In the second stage the tampon is introduced directly, without the aid of the speculum, and the liquid should also be carefully applied over the vulva. The operation must be repeated several times.

The pains of labor are due to the following causes, according to Professor Doléris:

First, the muscular contraction of the uterine walls. The pains from this source are usually slight, and cannot be affected by cocaine.

Second, pains are produced by the dilatation of the neck, and of the vaginal walls, the nerves of those parts being pressed upon and torn. These pains are relieved to a remarkable degree in many cases by cocaine.

Third, pains of an acute and severe character result from pressure of the child upon the nerve-trunks of the pelvis. Cocaine is powerless to relieve these.

Fourth, some pain is felt from the stretching of and pressure on the mucous membrane. This is suppressed by cocaine.

Fifth, most atrocious pains are produced in the expulsion of the head by the stretching of the vulva and perineum. These, also, according to Doléris and Jeannel, are relieved by cocaine.

The total result of the analgesic application seems to be that in most cases the patient feels but slight pain in the pelvis, and only complains of a dull pain above the pelvis, and pains in the loins.

It yet remains to determine whether the amount of cocaine used is ever sufficient to cause constitutional effects, or to affect the normal contractions of the uterus.

It appears very certain, so far, that cocaine is not so effective or convenient as chloroform, and its claim for adoption must be based on its greater safety and absence of any bad after-effects.

At present the most satisfactory use for cocaine at the time of labor is probably in cases of lacerated perineum. Here a hypodermatic injection of a few drops allows the immediate and painless suture of the parts.

THE DISSIPATION OF MAMMARY TUMORS BY UTERINE MASSAGE.

UNDER the title of "Hysterical Breast" Dr. Edward P. Fowler (*New York Medical Times*) reports in minute and careful detail three cases of hysterical women suffering from painful tumors in the breast, which disappeared solely, it would appear, as the result of manipulations directed to the womb. He says:

"From the three cases recited in this paper, together with several other confirmatory though less striking experiences, I am convinced that among other maladies connected with the female generative organism there is a class of breast-tumors, formidable in appearance, but which may be entirely controlled and dissipated by uterine manipulations, perhaps we might say uterine massage.

"From such experience as I have I should say that tumors of this kind are characterized by unusual hardness, freedom from attachments, great sensitiveness, especially upon light touch, absence of all other glandular swellings, hysterical temperament, and with more than an ordinary degree of sexual differentiation.

"I think they will generally be found in company with a tenderness in the upper cervical portion of the spine, sensitive ovaries, pressure upon which will give a sense of relief, even though it increases the pain, and with a uterine hyperæsthesia, unassociated with either ulceration or other inflammation.

"It probably would be most often associated also with a profusion of hair, heavy eyebrows, long lashes, and full lips, especially upper lip."

His first case was that of a young unmarried woman who had a tumor in the left breast about the size of a hen's egg. This was very tender, especially when attention was directed to it. The patient had a "never-ending pain" in the ovaries. Pressure upon them produced a sensation partly painful but partly pleasurable and erotic, and the pressure would throw the patient in a deep hypnotic sleep lasting from ten to sixty minutes.

The girl had had hysterical attacks, and some of the relatives were epileptic. A vaginal examination revealed nothing. Several distinguished physicians and surgeons had examined the tumor and advised its removal. Dr. Fowler, after a careful study of the case, decided to make the same recommendation, but delayed doing so until his next visit. To his surprise he was told that his "treatment" had greatly benefited her. Subsequent experience showed that the simple vaginal examination produced a steady improvement in the symptoms, the tumor grew smaller, and finally disappeared. The second and third patients gave histories of much the same character.

They are most instructive, as showing the marked influence of the generative organs over nutrition in such cases. It is well known that fibroid tumors apparently disappear spontaneously at times. In the present cases one can trace a tolerably clear connection between the relief of genital irritation and the disappearance of the new growths.

THE AUTOPSY UPON THE LATE KING OF BAVARIA.

GREAT interest attaches to the question of the alleged madness of the late King Louis of Bavaria. Many have hinted that his eccentricities were purposely exaggerated by those about him, and that he was not in reality insane. A leading English medical journal takes this view.

The full report of the autopsy, which we give below, will therefore be read with close attention. It seems that on June 8th Professor Von Gudden, Dr. Hagen, Professor Grashey, and Dr. Hubrich deposed under oath (1) that King Louis was suffering from a well-advanced form of mental disturbance known to alienists as paranoia (Verrücktheit); (2) that this form of disease was one of gradual, progressive development, and was, in his majesty's case, then incurable; (3) that through this disease the free will of thinking was completely destroyed, and he was permanently incapacitated for governing.

Such was the unanimous opinion of the physicians mentioned.

The post-mortem was made by Professor Rüdinger, in the presence of Professor Grashey, and Drs. Kerschensteiner, Halm, Hubrich, and Rückert. Marked changes of various forms and of a degenerative nature were found in the skull, brain, and meninges. These changes were partly abnormal developments, partly chronic inflammations of old and recent date, and are described as follows:

The scalp was very thick and enormously vascular. The skull was disproportionately small and asymmetrical. For example, the diagonal diameter from the left brow to the right side of the occiput was 17.2 ctm., while from the right brow to the left occiput it was 17.9 ctm. The skull was extraordinarily thin, its thickest portion being only 3 mm. The coronal and sagittal sutures on the inner surface of the skull were completely ossified. The longitudinal sinus was too much dilated posteriorly and narrowed anteriorly. There were several large and small bony protuberances on both sides of the inner surface of the frontal bone.

The dura mater was in general much thickened, especially over the frontal bone, where it was vascular and roughened. The left petrous bone showed a projection which corresponded to a depression in the temporal lobe. The tentorium was irregularly thickened, and on stretching appeared porous and friable.

All the blood-vessels of the base were filled with a dark fluid blood.

The brain, without the dura, weighed 1,349 grms., or about forty-three and a half ounces.

The arachnoid on both convexities of the cerebrum was thickened and milky-looking. At one place, about at the junction of the left first frontal and the ascending frontal, the pia and arachnoid membranes had become thickened and raised by fibrous proliferation. The skull over this point was almost as thin as paper.

In certain localities on both sides the convolutions appeared shrunken, viz., at the beginning of all three of the frontal convolutions, the mesal parts of the anterior central convolutions, and in the region of the middle of the post-central fissure. The brain substance was vascular and soft.

No microscopic examination has yet been made.

The account thus given apparently does reveal degenerative changes. Taken in connection with the personal and family history they place the insanity of the king beyond all reasonable doubt, and make it quite unnecessary to suppose that there was any dark conspiracy in connection with his tragic end.

THE CONTRIBUTORS TO THE MEDICAL RECORD.

DURING the year ending with June, 1886, there were received and published in THE MEDICAL RECORD four hundred and eighty-one communications from its readers and subscribers. A still larger number of articles was received, but for various reasons could not be published. This large number of communications is most gratifying, as showing the scientific activity, powers of observation, and literary diligence of the American physician. For at least four-fifths of these articles were from general practitioners, and represented the fruits of sound studies and of practical experience in the treatment of disease. The contrast between this state of things and that in France and Germany is striking. The number of contributions in the leading medical weeklies of those countries is perhaps one-half less, while the number of contributors is still fewer. Though open to some criticism, it is, on the whole, the better way that medical art should be advanced by the observations and contributions of the many rather than by the laborious studies and closet-work of the few. At least these methods usefully supplement each other. The American notes his results and reports them to THE MEDICAL RECORD or other journal, but the German and Frenchman appear to leave this mostly to their professors and their assistants.

It is naturally agreeable and consoling also to find how widespread is the interest taken in the columns of THE RECORD. We have received and published contributions from every State in the Union except Vermont, Delaware, and Florida.

A very considerable majority of our contributors are from outside the city and State of New York. Ohio, Pennsylvania, Maryland, and Illinois come first in the number of articles sent. But Massachusetts, Indiana, California, Missouri, and Kentucky follow closely after.

Quite a number of esteemed correspondents reside in Alabama, North Carolina, Wisconsin, Minnesota, Michigan, and the robust State of Texas. Thus THE RECORD'S columns receive equally solid support from the sunny fields of the South and the rock-bound coasts of New England. Physicians in Oregon, New Mexico, Nebraska, and Arizona, however, send us more than our neighbors in Vermont, New Hampshire and Rhode Island. The United States Army and Navy have furnished most valuable papers, and we yearly have, besides, communications from England, Mexico, Japan, Corea, and Palestine.

Without any desire to indulge in self-praise, we feel nevertheless that it is but right to say that this widespread and gratifying support of our columns is due to the steady and consistent purpose with which THE MEDICAL RECORD has aimed to present whatever appears in medical literature that could possibly interest, instruct, or benefit the general practitioner in his daily work. It has been our aim, also, to promote in every way the moral, social, and educational condition of those practising the high calling of medicine. In pursuing these ends, naturally local and geographical considerations entirely disappear; medicine is cosmopolitan, and of this there can be no better evidence than the columns of THE MEDICAL RECORD, upon whose contributors the sun never sets.

THE TRUE OBJECTS OF MEDICAL SOCIETIES.

DR. FRANCIS DELAFIELD, in his inaugural address at the opening of the Association of American Physicians and Pathologists, stated in a few pregnant sentences the objects of the Association. They told well the story of the objects of the new Society, but they might also be profitably used as a guide for all national and local Associations. He said:

"We all of us know why we are assembled here to-day. It is because we want an Association in which there will be no medical politics, and no medical ethics; an Association in which no one will care who are the officers and who are not; in which we will not ask from what part of the country a man comes, but whether he has done good work and will do more, whether he has something to say worth hearing, and can say it. We want an Association composed of members, each one of whom is able to contribute something real to the common stock of knowledge, and where he who reads such a contribution feels sure of a discriminating audience.

"We are all busy men, working men, ambitious men. We all like to give instruction and to gain reputation, and both of these we can do in the societies already existing. But we also want a society in which we can *learn* something. And this, I take it, is the real object of the enterprise which we inaugurate to-day: to form an Association of Physicians and Pathologists to which we may come year after year with the well-founded hope that at each meeting we will find something to *learn*."

SCARLET FEVER IN THE COW.

DR. JAMES CAMERON has reported the results of observations tending to show that cows may suffer from a peculiar, hitherto undescribed, infectious disease, and that consumers of the milk of these cows may get scarlet fever. His attention was attracted to the subject by an outbreak of scarlet fever which occurred in a certain district in and near London. It was found that the families in which the fever appeared used the milk from a certain dairy, the cows of which were affected by the peculiar disease in question. The disease is not exactly a new one, being known to farmers as "sore teats," "blistered teats," etc., but its nature has not been recognized. In veterinary text-books it is spoken of as "crythema mammillarum." Dr. Cameron believes it to be a specific contagious affection, occurring usually in the first instance among newly-calved cows, and capable of being communicated to healthy cows by direct inoculation of the teats with virus conveyed by the hands of the cowman. The disease may continue from four to six weeks, and is characterized by general constitutional disturbance, a short initiatory fever, a dry, hacking cough, sometimes quickened breathing, sore throat in severe cases, discharges from the nostrils and eyes, an eruption on the skin round the eyes and hind quarters, vesicles on the teats and udder, alteration in the quality of the milk secretion, and well-marked visceral lesions.

As it is admitted, we believe, that scarlet fever may be disseminated by milk, the importance and interest of Dr. Cameron's observations are at once apparent.

Scarlatina has been described by Professor Barlow as affecting the cow, but the clinical description given is more like that of purpura hæmorrhagica.

THE REVENUE MARINE AND NATIONAL QUARANTINE.

THE Executive departments of our Government certainly present some curious anomalies. Among the latest is that of the Treasury Department patrolling the coast with steamers for the purpose of keeping out infectious diseases. The object is a commendable one, but it is very remote from national finance. The Secretary of the Treasury, some weeks ago, issued an order to the officers of the Revenue Marine to the effect that the President had "determined to establish, by means of the vessels of the Revenue Marine, a national patrol of the coast of the United States, so far as it may be practicable under existing law, and consistent with the performance of the other duties confided to that service."

The revenue steamers are directed to "cruise actively," speak all vessels from southern or foreign ports, and if any contagious disease is found, to send the vessel to the outer quarantine of the destined port. The quarantine-officers to be recognized by the service are the medical officers of the Marine Hospital Service and local or State officers.

LAPAROTOMY IN AMERICA.

WHEN *The Lancet* made some incorrect criticisms of American work in connection with laparotomy for abdominal wounds, THE MEDICAL RECORD was the only American medical journal to see and point out the injustice done. For this we have received no thanks from our esteemed but less alert contemporaries; on the contrary, we have been attacked with the whole artillery of literary weapons, from gentle words of sadness and reproach to burning sentences of indignant denunciation.

Our sin, we believe, was in not mentioning Dr. Parkes' dogs, thus putting, we are told, a deliberate slight upon the whole West and South.

Our contemporaries, who have been so quick to see our deficiencies, should have read *The Lancet* and corrected it themselves. We made our criticism and did not attempt to give the whole history of laparotomy.

If we had we should have been obliged not only to do justice to Dr. Parkes, but we should have had to speak of Nothnagel's experiments in 1883, showing how a bowel may be strangulated by a mechanical irritation; of the eight or ten successful cases of laparotomy for stab-wounds performed by foreign surgeons; of the perfectly unique case of laparotomy for rupture of the intestine performed by a London surgeon, Mr. Owens; of the laparotomies for septic peritonitis performed, up to a recent date, almost exclusively by foreign surgeons (we speak of surgical not gynecological cases); of Jobert's experiments upon dogs; of the cases of successful laparotomy for pistol-shot wounds done by Kocher, Ramsay, and Legouest, already numbering more than those done in this country.

Perhaps if our critical contemporaries were more familiar with the history of the subject, they would be less inclined to blame us for not turning an editorial note into a historical and bibliographical monograph.

It is perfectly true that laparotomy for wounds of the abdominal viscera was conceived and perfected in America, and that Dr. Parkes' dogs were therein *magna pars*. It is possible that the same idea was conceived abroad, however, and it is certain that already more successful cases of this kind have been reported by European than by American surgeons.

News of the Week.

Remarkable Lesion of the Nerve-centres in Leucocythæmia.—Dr. Byron Bramwell reports (*British Medical Journal*) a typical case of leucocythæmia in which the vessels of the nerve-centres presented remarkable varicosities. He thinks also that he observed micrococci in the substance of the superior cervical ganglia. It is thought that this condition of extraordinary vascular dilatation and extravasation may not be unusual in leucocythæmia, although no cases of the kind have hereto fore been put on record.

Lister and Antisepsis.—Sir Joseph Lister is said to be making extensive trials of various non-volatile antiseptics, double chlorides, and double cyanides of mercury chiefly, and with results which appear to be most satisfactory. In addressing his class, after operations, Sir Joseph Lister speaks with all his former confidence as to the healing of wounds under the simpler methods at present employed, which do not now include the troublesome spray or impervious waterproof dressings.

Poisonous Asparagus.—We learn from the *Lyon Medical* that asparagus grown in certain localities becomes impregnated with minute amounts of sulphide of carbon. Persons eating this are affected with violent colic and diarrhœa.

Professional Amenities in Boston.—One year ago a homœopath, Dr. Conrad Wesselhoeft, by invitation, gave his views upon homœopathy to the Boylston Medical Society of the Harvard Medical School. On April 15th last, Dr. V. G. Bowditch, President of the Boylston Medical Society, delivered an address before the Hahnemann Society of the Boston University, on homœopathy as viewed by a member of the Massachusetts Medical Society.

Professor Kaposi succeeds the late lamented Professor Auspitz as editor of the *Archivs für Dermatologie und Syphilis*.

The Rhode Island Medical Society, at its seventy-fifth annual meeting, held at Newport, June 10th, elected the following officers: Dr. Horace G. Miller, President; Dr. Albert Potter and Dr. John W. Mitchell, Vice-Presidents; Dr. George D. Hersey, Recording Secretary; Dr. E. M. Harris, Corresponding Secretary; Dr. Charles H. Leonard, Treasurer. The Trustees of the Fisk Prize Fund awarded two prizes of $200 each, as follows: (1) To Dr. Charles V. Chapin, of Providence, for the best essay on "Methods of Treatment and Practical Results of Malarial Diseases in New England"; (2) to Dr. Hobart Amory Hare, of Philadelphia, for the best essay on "New Methods and Modified Forms of Disease, due to Progress of Modern Civilization in the Last Half Century." Two prizes, of $200 each, were announced for the ensuing year, to be awarded for the best two essays on these subjects: (1) "Antiseptic Midwifery in Hospital, Dispensary, and Private Practice"; (2) "Membranous Enteritis."

A Correction.—Dr. B. A. Watson, of Jersey City, writes: "In the report of the transactions of the recent meeting of the New Jersey State Medical Society, I am erroneously quoted as saying that I had made use of cocaine as a local anæsthetic in amputation of the thigh, and also that I objected to this use of the drug. What I did say was, that I had *witnessed* an operation (the operation—amputation of the thigh—was done by Dr. Varick, who so far as I know was the first to use cocaine in major amputations) in which cocaine was used as a local anæsthetic, and that, owing to the *severe mental suffering* in these cases, I did not approve of cocaine as an anæsthetic in major operations, except in cases where sulphuric ether could not be given with safety. I shall be pleased to have this matter corrected in the columns of The Record."

The Suit brought against Dr. B. A. Watson, of Jersey City, by the Society for the Prevention of Cruelty to Animals, is most unjust and iniquitous. Dr. Watson's experiments with dogs were conducted for the purpose of solving one of the most obscure and perplexing problems in pathology, viz., that of spinal concussion. It is greatly to be regretted that they have been interfered with.

A Good Thing to Cultivate.—The art of thinking, then, is well worthy of cultivation, whether the individual is naturally endowed with logical capacity or represents only indifferent ratiocinative capacity.—*New York Medical Monthly*.

Mode of Payment of Fees in Vienna.—In Vienna it is usual to give medical men their fees at the end of the attendance, so that when honoraria are offered the hint is understood, and no more visits are paid without further request. Some time since a practitioner was sent for to see the child of a certain tailor, whom he found suffering from fever, but with no signs enabling a diagnosis to be made. The fee was given, and the doctor, hearing nothing further, did not consider his services were required again. However, it was discovered by the police, shortly afterward, that some of the children in the tailor's house were suffering from small-pox. The tailor and the doctor were both summoned, the latter being acquitted, while the former, who was shown not only to have concealed the existence of the disease, but to have taken in work at the time, was sentenced to ten days' imprisonment.

A Bacteriological department will be opened in connection with the Pathological Institute at Berlin, presided over by Professor Virchow. It is probable that Dr. Israel will be nominated director of the department.

Reforms in Spanish Medical Study.—Some much-needed reforms, says *The Lancet*, are in contemplation by the Ministry of the Interior regarding the regulations affecting medical study in Spanish universities. Though no addition will be made to the duration of study, the course for the license will be better arranged, so that preliminary subjects will be necessarily studied during the earlier portion of the student career, *e.g.*, histology, which at present is considered an advanced subject, is to be divided into normal histology for first-year's men, and pathological histology for third-year's men. Besides this, elementary clinical study will be included in pathology, and a new subject, viz., the diseases of children, will be added. The doctorate will consist of three subjects, the history of medical sciences, chemical analysis, and public hygiene, including the geographical and historical study of epidemics. The students will also be allowed to visit and practise in the provincial hospitals.

Whooping-cough Successfully Treated by Insufflations of Quinine.—Dr. J. Bachem, of Bonn, has treated sixteen cases by blowing into the nostrils a mixture of quinine muriate and powdered gum arabic (3 to 1). The application was made once or twice daily, and the disease was cured in almost all cases in about three weeks.

Enormous Negro Mortality.—In many Southern cities, large and small, the negro mortality-rate is nearly double that of the white population. But in Savannah, Ga., according to the *Times-Democrat*, while the annual mortality-rate among the whites is 12.19, that among the negroes is 122.94; and among negro children under five years of age 601.93 per 1,000.

The Vermont State Medical Society at its last annual meeting had a very active discussion on the subject of Ethics. Several prominent members frankly confessed that they consulted with some homœopaths, and not with some so-called regulars. The general sentiment seemed to be that the society should either conform to its Code or abolish or change it. Definite action will be taken at the next annual meeting.

Pasteur has lost still another patient. The sum of over one million francs has been subscribed to the Pasteur Institute.

Discovery of the Microbe of Rabies.—Dr. G. F. Dowdeswell, announces in *The Lancet* that he has discovered the microbe of rabies. He says: "It is a micrococcus, not very minute, and of the usual form. It stains, however, with some difficulty; and this accounts for its having hitherto escaped observation. In the cases of dogs which I have as yet examined, its principal seat is evidently the central canal of the spinal cord and medulla oblongata; thence it pervades the other tissues of the central nervous system, occurring (sometimes in vast masses) around the walls of the blood-vessels, and in some cases within the vessels among the red blood-corpuscles. In the cortex of the hemispheres I have found it, but in very small numbers, and, so far, only in the perivascular and peri-cellular lymph-spaces. In the cerebellum I have not found it at all, neither have I as yet succeeded in finding it in the salivary glands. I shall shortly publish the methods by which it may be stained with certainty. I must, however, state that it does not stain by hæmatoxylin, either with or without a mordant, as asserted by Fol. I have repeated his methods carefully. Neither does it occur within the nerve-fibres, as he states; and, lastly, it is fully three times the dimensions which he gives. I may add that it does not occur in the same situation, treated by the same methods, in normal animals. In the one case of a rabid dog, which I had examined to control my previous observations, the tissues were placed in alcohol so shortly after death as to preclude the possibility of the occurrence of septic organisms. In addition to which, all saprophytes, as far as yet observed, stain very readily with the usual aniline dyes, which this microbe does not. I must point out, in justice to the genius of Pasteur, that these observations on the occurrence of the microbe go far to confirm his statement of the seat of the virus; it may further afford a means of diagnosis in any doubtful case." Preparations of the microbe were shown at the meeting of the Royal Microscopical Society on the 9th ult.

Professor Von Langenbeck was recently operated upon by Professor von Pagenstecker, for cataract. The operation, we learn, was a successful one.

Apomorphine as a preventive of epileptic attacks is highly recommended by Vallender, who uses it hypodermatically in the usual doses.

Ringworm in a New-born Infant.—A correspondent of *The Lancet* writes that a lady, who for some time past had had a dread of ringworm appearing in any of her children, was delivered of a female child which was found to have several spots of ringworm on its body and one on the scalp. These have gone on increasing, and now rather an extensive surface of the back is covered with the rings. The writer asks if it is not unusual for this affection to appear in a child of that age.

Long-lived Professors.—It is said that there are at present at the various German universities no fewer than 157 professors between the ages of seventy and ninety. Of these, 122 deliver their lectures as usual.

Reports of Societies.

THE ASSOCIATION OF AMERICAN PHYSICIANS.

First Annual Meeting, held at Washington, D. C., June 17 and 18, 1886.

THURSDAY, JUNE 17TH—FIRST DAY—MORNING SESSION.

THE first meeting of the Association of American Physicians was held in the Army Medical Museum, Washington.

The meeting was called to order by the President, DR. FRANCIS DELAFIELD, of New York.

ABSTRACT OF PRESIDENT'S ADDRESS.

It was my intention to say some words concerning the objects of the Association, and the best methods of carrying these objects into effect, but when I considered the character and attainments of those whom I was about to address, such a plan seemed to me unnecessary and even impertinent.

We all of us know why we are assembled here to-day. It is because we want an Association in which there will be no medical politics and no medical ethics; an Association in which no one will care who are the officers and who are not; in which we shall not ask from what part of the country a man comes, but whether he has done good work and will do more; whether he has something to say worth hearing, and can say it. We want an Association composed of members, each one of whom is able to contribute something real to the common stock of knowledge; and where he who reads such a contribution feels sure of a discriminating audience.

We are all busy men, working men, ambitious men. We all like to give instruction and gain reputation, and both of these we can do in the societies already existing; but we also want a society in which we can *learn* something. And this, I take it, is the real object of the enterprise which we inaugurate to-day—to form an association of physicians and pathologists to which we may come year after year with the well-founded hope that at each meeting we shall find something *to learn*.

Without further preface I shall ask your attention to a subject of much practical importance:

CHRONIC CATARRHAL GASTRITIS.

The fact that the lining membrane of the stomach is both a mucous membrane and an organ of digestion does, in a measure, confuse our appreciation of the inflammations of this membrane. We are apt to notice especially the disturbances of digestion, and to include all the cases in the general class of gastric dyspepsia.

But the lining membrane of the stomach is, in part, a mucous membrane. It is frequently the seat of chronic catarrhal inflammation, and it then behaves as do the other mucous membranes under the same circumstances.

Now let us turn to the consideration of chronic catarrhal gastritis. Whether we consider the cases which are found at autopsy, or the cases seen during life, it is evident that in the majority of persons the inflammation goes no further than to affect the function of the mucous glands. They constantly produce a thick, tenacious mucus, which adheres in a thick layer to the surface of the mucous membrane. Less frequently the mucus is thin and fluid, and is vomited. With such a change in the mucous glands, the peptic glands may also give evidence of disordered function; but it is important to remember that unimpaired gastric digestion is perfectly compatible with chronic catarrhal gastritis.

Chronic catarrhal gastritis may mean, 1, that the mucous glands produce too much mucus; 2, that, in addition, the functions of the peptic tubules are affected; 3, that the structure of the mucous membrane is so profoundly changed that its digestive functions are anatomically impossible; 4, that from relaxation of the muscular wall, or stenosis of the pylorus, the food is not entirely discharged from the stomach, but portions remain.

The ideas which one has as to the causes of chronic catarrhal gastritis will vary somewhat according to the experience of the hospital autopsy-room and the character of the cases observed in private practice. In the autopsy-room we find more of the cases associated with complicating diseases, or exhibiting the very advanced lesions of gastritis. Organic disease of the heart, emphysema of the lungs, cirrhosis of the liver, Bright's disease, phthisis, and alcoholism are evidently in most of the cases the causes of the gastritis. In private practice, on the other hand, I find most of the cases in adults between the ages of twenty-five and fifty; a smaller number in children and in old persons. In the majority of the cases no cause is to be discovered other than the mode of life and the character of the locality in which the patient lives. The same climatic conditions which predispose to chronic naso-pharyngeal catarrh and chronic bronchitis, have the like effect as regards chronic gastritis. In a smaller number of cases other causes can be discovered. An attack of acute gastritis, or of gastro-duodenitis, or of gastro-enteritis, may be followed by chronic gastritis. Typhoid fever and the malarial fevers may be accompanied with an acute gastritis which may assume the chronic form. In some women the disease seems to begin during pregnancy. Alcoholism and the abuse of drugs furnish their quota of patients. Rheumatism and gout are sometimes unquestionable causes. Cirrhosis, Bright's disease, emphysema, phthisis, and cardiac disease also furnish a certain number of cases.

The first among the symptoms comes pain, varying from a mere feeling of oppression or discomfort to the most severe and agonizing pain. Most common is the feeling of uneasiness or discomfort, either following the ingestion of food or occurring when the stomach is empty. It is not always easy to distinguish this from pain belonging to the small intestine or to the colon. Much worse is the severe pain due, in some cases, to the presence of food in the stomach, a pain which is often followed by vomiting. At first it only comes on when the stomach contains a considerable quantity of food, but later continuing, even after repeated vomiting, so long as the smallest fragment is left. It is so severe that the unfortunate sufferer has no rest by day or by night, deprives himself of almost all nourishment, and finally falls a victim to the opium habit.

Nausea and vomiting are also regular symptoms. The nausea belongs to the early morning hours. The vomiting is most frequently a vomiting of food either in considerable quantities, or vomiting kept up so long as the smallest particle of food is left in the stomach. In other cases large quantities of brownish fluid, mixed with mucus and food, accumulate in the stomach and are vomited from time to time. This is especially the case when the stomach is dilated. Vomiting of pure mucus is seen in a few cases. Vomiting of blood, usually not in large quantities, may occur. Regurgitation of acid fluid, in the morning especially, belongs to alcoholic gastritis.

Retention and fermentation of the food in the stomach are most common with the dilated stomachs, but are by no means confined to them. They are found often enough in other cases of chronic gastritis.

Constipation seems in some cases to depend directly upon the gastritis, and will disappear as this improves without the use of any laxatives. In the same way there are diarrhœas which can be cured by treatment directed to the stomach.

Headache is a symptom. It may follow a variety of types, but perhaps the most common is that which comes on at intervals.

A general loss of health, of which emaciation and loss of muscular strength are the most prominent features, is found with the worst cases of the disease. Inflammation of the tongue and a variety of abnormal sensations referred

to the throat, mouth, and tongue belong to some of the cases.

These are the most marked symptoms which may be referred to the gastritis directly. In the complicated cases, of which there are many, other symptoms are added which it is not necessary to consider at the present time.

The course of the disease is naturally prolonged over many years, and interrupted by periods of improvement. The symptoms come on in attacks, at first not severe, not of long duration, easily relieved in a variety of ways. As the disease continues, each succeeding year marks a greater severity and longer duration of the symptoms.

In attempting to establish a satisfactory treatment for chronic gastritis it is important to state as clearly as possible the problem to be solved. First, we must remember that all patients who suffer from gastric symptoms do not necessarily have chronic gastritis. Besides those who have functional disturbances of the stomach, or cancer or ulcer of the stomach, we find many others in whom gastric symptoms are due to diseases of other parts of the body. Anæmia, uterine disease, the neurotic and hysterical condition, and constipation, often behave in this way. In old people the function of gastric digestion is often impaired simply as a result of old age. To each one of these conditions belongs its appropriate treatment, but it is not the treatment of chronic gastritis.

Still further, we must remember that in many cases of gastritis, palliation of the symptoms is all that we can hope for. After excluding all these there remains a large and important group of cases of chronic catarrhal gastritis, in which we may hope not only to alleviate the symptoms but to cure the disease.

It is evident from the nature of the disease that any treatment intended not merely to palliate, but to cure, must be of long duration, and that it must be repeated from time to time when the inevitable relapses occur. The different plans of treatment which may be adopted are: the curative treatment of climate and mode of life, the regulation of the diet, the administration of drugs, and the use of local applications directly to the inflamed membrane.

Climate and mode of life, I believe, offer the most certain means of curing chronic gastritis. The two points of importance are, first, the locality selected must be one where the patient can live an out-of-door life; and second, the patient must live in this climate either for several years or for a considerable part of each year. Excellent as this method of treatment is, it is evident that it can be carried out only by a limited number of persons.

The regulation of the diet is a matter which demands consideration in every case of chronic gastritis. In trying to ascertain the best way of feeding these patients I have found only one satisfactory method, and that is to feed them experimentally with different articles of food, and then, after an interval of several hours, wash out the stomach and see how thoroughly these articles of food have been digested and removed from the stomach. After pursuing this course for a number of years I have arrived at the following conclusions:

It is necessary that the patients should be well fed, a starvation diet never answers.

The stomach does not require any rest from the performance of stomachic digestion; on the contrary, it is all the better for being called upon to perform its natural function.

The patients' own ideas as to what food agrees with them are usually erroneous. They are apt either to starve themselves, or to select the least nutritious articles of food.

The use of artificially digested foods, or of substances such as pepsin to assist stomachic digestion, is unnecessary.

The starches, oatmeal, corn-meal, bread, the cereals, the health-foods, are, as a rule, bad. Portions of them remain undigested in the stomach for many hours.

Milk in adults is an uncertain article. It answers very well for some persons, not at all for others.

Meat is usually readily and well digested, but there are occasional exceptions to this rule.

Vegetables and fruits can be eaten, but the particular varieties must be selected experimentally for each patient. I do not believe that any case of chronic gastritis is to be cured by diet alone.

The advantageous use of drugs belongs to the earlier stages of chronic gastritis. At that time they often palliate symptoms, and sometimes even seem to cure the inflammation. In the later stages of the disease their use becomes more and more unavailing.

The use of local applications, made directly to the mucous membrane of the stomach, I regard as the most efficacious plan of treatment for those patients who are not able to leave home and seek a proper climate. The local applications are readily made by the introduction of a soft-rubber tube through the œsophagus into the stomach. Liquid applications are the best. They should be made in such quantities as to come thoroughly into contact with the entire surface of the mucous membrane, although the pyloric end of the stomach is the region where the inflammations are principally situated. They should be made at a time long enough after eating for the stomach to be as nearly empty as possible.

For many cases warm water alone, in considerable quantities, is the only local application needed. In some, however, there is an advantage in medicating the water, and for this purpose I employ a variety of substances. The alkalies, the mineral acids, bismuth, carbolic acid, the salicylates, iodoform, belladonna, ipecac, gelsemium, may each one be employed according to the particular case.

For the first week of this treatment it is wise not to expect any special improvement. Indeed, even a longer time than this may try the perseverance of the physician and the confidence of the patient. Sooner or later, however, the expected improvement begins; the nausea and vomiting cease, the constipation or diarrhœa is improved, the flatulence is no longer troublesome, the headache becomes less frequent, and of more real value than these, the improvement in the general condition of the patient becomes evident. The color, the weight, the appetite, the sleep, the spirits of the patient all show a change for the better. Of all the symptoms the pain is the one which is apt to persist the longest.

For two or three months the patient has to be kept under observation, and the applications to the stomach made by the physician. After this the patient is dismissed, but continues the treatment himself, first every other day, then twice a week, then once a week for several months. The regular relapses of the disease are managed in the same way, but are much more quickly relieved.

I have tried thus succinctly to lay before you the characteristics of a common and important disease, and yet a disease which seems to me not to meet the recognition and attention which it demands. If I can secure for the patients who are made miserable by it a more careful and intelligent management than they are now apt to receive, the purpose of this paper will be answered.

The Committee on Permanent Organization reported a constitution and by-laws. Adopted. The main provisions of the constitution are: That the Association has for its object the advancement of scientific and practical medicine. It shall be known as the Association of American Physicians, and shall hold its annual meeting in the month of June, in the city of Washington, D. C. That the proceedings shall consist of discussions on subjects of general interest in the departments of medicine and pathology; of original communications and of demonstrations of gross and microscopic preparations; of apparatus and of instruments. That there shall be members and honorary members. The number of members shall be limited to one hundred. Physicians of sufficient

eminence to merit the distinction may, to a number not exceeding twenty-five, be elected honorary members, and as such shall be entitled to attend all meetings and take part in the proceedings, but not to vote upon business questions. That nominations for membership shall be signed by two members, be referred to the censors, and be acted upon at the succeeding meeting.

The following Nominating Committee was then appointed to report on Friday morning: Drs. James Tyson, A. Brayton Ball, George B. Shattuck, Frank Donaldson, and Hosmer A. Johnson.

The first paper was entitled,

TENDON-JERK AND MUSCLE-JERK IN DISEASE, ESPECIALLY WITH REFERENCE TO POSTERIOR CLERKING OF THE SPINAL CORD,

by S. Weir Mitchell, M.D., of Philadelphia, and Morris J. Lewis, M.D., of Philadelphia.

It was stated that while a muscle or a nerve may be excited by both electrical and mechanical irritation, the former is to be regarded as a ruder agent than mechanical stimulus. In some cases electricity is inapplicable beyond a certain extent. It was held that the knee phenomenon was a direct muscular response and not due to reflex action. The most delicate test for determining the condition of the muscle is by striking the stretched tendon. This can be done in various situations, as at the knee, ankle, elbow, and jaw. Every distant muscular exertion, such as winking, if accurately timed, exaggerates these phenomena. To demonstrate this the patient should lie down with the knee slightly bent. At the time that the tendon is tapped, or just before, the patient is directed to wink, and it will be noticed that the jerk is much increased. A decided sensation, such as heat, cold, or an injury will increase the responsive power of the muscle or tendon which has been struck. Both the tendon- and the muscle-jerk are reinforced by irritation of distant parts. This reinforcement disappears when the muscles are cut off from the spinal centres.

A blow on the muscle causes the muscle-jerk to extend up and down, but not transversely. In some cases of disease this jerk is irregular. In addition to this contraction the muscles may form a little eminence or mound, which disappears slowly. Late in ataxia this is unusually well marked. It is also observable in some healthy muscles.

The phenomenon of reinforcement was attributed to an increase of tone in the muscle as a result of the distant irritation.

A tabular statement was then presented, giving the results of observation in twenty-three cases of locomotor ataxia. In this table the various symptoms and signs presented were represented by signs. In this way the history of each case could be seen at a glance.

In the first stage of locomotor ataxia the tendon-jerk is diminished or absent, while the reinforcement is fair. In the subsequent stages both the tendon-jerk and its reinforcement are absent. The muscle-jerk and its reinforcement continue normal through the first two stages. In the third stage, while the muscle-jerk is normal, the reinforcement is absent. In the fourth stage the muscle-jerk is increased, while the reinforcement is absent. In the fifth stage the muscle-jerk is diminished, and the reinforcement is absent. In the sixth stage both the muscular jerk and the reinforcement are absent. The increase of the muscle-jerk, late in the disease, may be due to some irritative changes in the muscle, but this has not been positively determined.

In regard to associated movements, in a certain proportion of cases, if the patient is directed to shut his right hand, the left hand will also shut to a certain extent. And if the patient is sitting down the leg may be drawn up. This condition has become more marked as the ataxic condition has increased.

Another symptom referred to, and which was considered a new symptom, was prominence of the eyeballs. While the condition is not as marked as in exophthalmic goitre, it is sufficiently distinct to be apparent if attention has been called to the matter.

Dr. E. C. Seguin, of New York, suggested that when the patient performs some movement, or when his attention is attracted by excitation of a sensory nerve, the cerebral inhibitory influence over the spinal cord is momentarily reduced, and the reflex powers are raised for the moment. The reinforcement seemed to be rather a negative condition.

Dr. H. C. Wood, of Philadelphia, thought that the explanation of the knee-jerk was based on physiological ideas. There are three classes of movements, the voluntary, the reflex, and movements originating in the muscle or in the nerve-endings in the muscle. Until the fact that the time of the knee-jerk is so different from the time of the other reflexes is explained, we must consider that we have these three classes of movements. It is possible that the movements in the muscle are the result of inhibition, but at present we have no proof that such is the case.

Dr. F. Peyre Porcher, of Charleston, S. C., read a paper on

TYPHOID FEVER.

The author described a method of treatment which he considered very satisfactory. As in all cases of high temperature, there is costiveness, the result of the arrest of the intestinal secretions. He recommended a mild laxative at the beginning of the treatment. Any laxative may be employed.

In the treatment of typhoid fever three things are to be considered; the necessity for maintaining the strength of the patient, the support of the system by the use of stimulation, and the morbid effect of high temperature. Special attention was directed to the latter element of the treatment. In reducing the temperature, the speaker had resorted to the use of ice-cold water, which was applied to the head, hands, and arms by the use of towels wrung out of the water and reapplied as frequently as necessary. The applications are continued for ten to fifteen minutes, until the heat of the skin is reduced. The use of baths was considered objectionable, on account of the difficulty of their application, and on account of the prejudice against them. He prescribes for internal use a fever mixture, prepared as follows:

℞. Potassii acetatis ..... ʒ j.
Liquor ammonii acetatis ..... ʒ j.
Spt. ætheris nitrosi ..... ♏ ss.
Tinct. aconiti ..... ♏ ss.
Aquæ ..... ad ℥ iv.

Sig.—A dessertspoonful in a little water, every two hours, so long as the fever continues.

Morphia or the bromides may be added to the above preparation. It may also be employed in other fevers.

Hot pediluvia may also be employed. In malarial cases quinia and arsenic are employed. Later the use of the mineral acids are added. With reference to the use of stimulants, these may be continued as long as the tongue is dry. Oil of turpentine is often called for on account of tympanitic distention of the abdomen. It is also of value as an astringent, and as a general stimulant. The speaker had treated thirty cases in private practice in this manner, of which number three died. In these cases there were causes sufficient to explain the fatal termination.

Dr. James Tyson, of Philadelphia, described a case in which, to reduce the temperature, he wrapped the patient in a sheet which was kept constantly wet with ice-water. This was entirely successful. In this case both antipyrine and thaline were employed, but although they promptly reduced the temperature it soon returned to its original position. When it is necessary to keep the temperature continuously reduced, some modification of the cold pack is, I think, the best method.

Dr. James T. Whittaker, of Cincinnati, referred to the possibility that the high temperature might be nature's way of getting rid of the poison. It has been found that the virulence of the typhoid-fever bacillus can be reduced by heat. It is also possible that the changes formerly attributed to heat may be due to bacilli.

Dr. E. Darwin Hudson, of New York, described the plan of treatment employed at Bellevue Hospital. The treatment is almost negative, consisting in sponging the patient every two hours during the continuance of the temperature above 102.5°, and adherence to an absolute milk diet. The only other measures employed are those directed to the relief of special symptoms occurring in the course of the disease.

Dr. Samuel C. Chew, of Baltimore, referred to the use of quinia by hypodermic injection, in order to reduce the temperature. It seems to have almost a specific action when used in this way.

Dr. William H. Draper, of New York, said that there was, perhaps, nothing more fallacious than statistics in typhoid fever. Cases of fever not truly typhoid are confounded with specific typhoid fever. We have all seen cases in which there was a continued fever, but in which the temperature did not run the typical course. I think that in such cases we have no evidence that they are cases of typhoid fever.

He thought that in the majority of cases the value of antipyretics is not so much in reducing the mortality, but in affording comfort to the patient. The mortality of typhoid fever in the majority of cases depends upon conditions over which a reduction of the temperature would have no influence.

Dr. William Pepper, of Philadelphia, thought that we should be slow in accepting a mortality of fifteen or even ten per cent. as evidence of much success.

An excellent rate of mortality, he thought, could be secured by absolute rest from the first moment of suspicion, and a rigid diet of milk or milk diluted. In addition, he believed that the abstraction of heat by the use of cold water is of great value. A remedy directed to the constant and important lesion of typhoid fever aids in reducing the temperature. Under proper treatment he thought that the mortality should not exceed five or six per cent.

Afternoon Session.

The first business of the afternoon session was the discussion of the question:

DOES THE PRESENT STATE OF KNOWLEDGE JUSTIFY A CLINICAL AND PATHOLOGICAL CORRELATION OF RHEUMATISM, GOUT, DIABETES, AND CHRONIC BRIGHT'S DISEASE?

Dr. James Tyson, of Philadelphia, referee; Dr. William H. Draper, of New York, co-referee.

Dr. Tyson, the referee, began by defining the diseases included in the subject. The usual definitions of rheumatism and gout, as general diseases with local expressions, were given. Diabetes was subdivided into two varieties, the milder and the more severe form. The former consists essentially in a defect in that particular metabolic office of the liver by which glucose is converted into glycogen. It is due to over-stimulation of the liver-cells by the excess of absorbed glucose arising from the habitual over-use of saccharine and starchy foods. The more severe form of diabetes may be termed neurogenous, and is caused by some direct or reflex influence on the vaso-motor centre, whence arises a hyperæmia and accelerated circulation through the liver, as the result of which the glucose absorbed during intestinal digestion is carried too rapidly through the liver to permit its conversion into glycogen. To this is added, in advanced stages, glycogen resulting from the splitting up of the products of digestion of nitrogenous foods.

Taking up the discussion, first as to rheumatism and gout, the referee called attention first to the difference in the morbid anatomy of the two diseases, in the absence of anything specific or peculiar in the changes in the joints in rheumatism, while in gout there is the peculiar deposit of sodium urate in the joints or their vicinity. The composition of the blood is definitely altered in gout by the almost constant presence of an excess of uric acid in combination with sodium, whereas no change of corresponding importance is found in the blood of rheumatism. Heredity plays a much more important rôle in gout than in rheumatism, reaching, in the former, according to various observers, to fifty to one hundred per cent., while in rheumatism the maximum claimed is thirty-four per cent. The early age at which rheumatism presents itself, as compared with gout, implies a difference in the etiology, as does also the absence of renal and the presence of cardiac complications. Alcoholic liquors and over-indulgence of food have no influence in the causation of articular rheumatism. In gout they are all-powerful.

The exciting cause of rheumatism is always cold, dampness, or both. The cause of the explosion or the acute attack of gout is the cause of the disease itself, and is due either to the over-accumulation of uric acid in the blood, whether as the result of increased formation or defective elimination, or to diminished power of resistance of the organism through some accidental cause, atmospheric or physical.

Moreover, except in the case of salicylic acid, which is admitted by all to be useful in both affections, Dr. Tyson thought that the treatment required by the two diseases was different. The treatment of gout is eliminative, that of rheumatism restorative. It is true salicylic acid is efficient in both diseases, but this is not sufficient proof that they are the result of the same cause, so long as that cause is so easily demonstrated in one and not in the other.

The relation of gout to that form of chronic renal disease known as chronic interstitial nephritis is a true correlation, since there is every reason to believe that the cause of gout is one of the causes of this form of chronic renal disease so common in gout, and the evidence of renal disease is often found long before the gout manifests itself.

To estimate the relation between gout and diabetes, it is necessary to remember that there are the two forms referred to. With neither of them is there any pathological relation. Between gout and the first or mild form of diabetes there is a clinical correlation, although many of the facts on which it has been founded the referee believed to be erroneous. Thus, although uric-acid sediments are quite common in diabetes, yet careful quantitative analysis shows no increase in the amount of uric acid excreted. The uric-acid sediments must, therefore, be the result of the excessive acidity so characteristic of diabetic urines, due to the fermentative processes.

Again, it is said the lithæmic urines often contain sugar. This he was confident was much rarer than is commonly supposed, because of the fact that uric acid reduces the salts of copper, and this reaction is mistaken for that of sugar. He thought that the inability of gouty persons to digest saccharine and starchy elements of food should not be regarded as a proof of clinical correlation, because it simply indicates a feeble converting power of the intestinal digestive fluids over the carbo-hydrates. In diabetes there is no defect of this kind. The carbohydrates are converted into glucose with facility. The trouble is with the liver, which is not able to reconvert the glucose into glycogen.

Between gout and the more severe form of diabetes, which is the result of disease at a point distant from the liver, there is no correlation, either clinical or pathological.

Between diabetes and Bright's disease there is a relation of this kind. The effect of the circulation through the kidneys, surcharged with sugar alone, or with sugar,

acetone, and diacetic acid, is to irritate the renal cells and produce a degree of chronic parenchymatous nephritis instead of the interstitial nephritis which is so closely correlated with gout. From recent observations there is reason to believe that these changes take place in the kidney much earlier than used to be supposed, and that albuminuria appears correspondingly early, either coincidentally or in alternation with glycosuria. The difference between the relation of gout to Bright's disease and of the more severe or neurogenous diabetes is, that in the former that which causes the gout causes the Bright's disease, so that there is a true correlation, whereas in neurogenous diabetes, it is a result of the diabetes which causes the renal complication.

As to diabetes and rheumatism, the idea that these two diseases are closely correlated has apparently received substantial support from the results of treatment of the two diseases by salicylic acid. Occasional reports as to the efficiency of salicylic acid in diabetes have acquired additional impulse from views which have recently been promulgated by Latham, who concludes, on clinical grounds, that there are two forms of diabetes—one due to neurotic disturbances of the function of the liver, and the other due to neurotic disturbances of the functions of muscle. As the result of the latter, glucose is formed in the muscles and passes thence into the circulation. This latter is so closely related to rheumatism, that one degree of oxidation develops the materies morbi of rheumatism, and another develops glucose. Having shown also by the same reasoning that the administration of salicylic acid arrests the formation of uric acid, lactic acid, and glucose, he thus explains the usefulness of salicylic acid in some forms of diabetes, and says that in doses of from ten to twenty grains three times a day, he has seen it produce marked improvement. More recently, Holden reports the successful treatment of six cases of diabetes with salicylic acid.

The referee, whose experience with salicylic acid in the treatment of diabetes had not heretofore furnished satisfactory results, had not yet had the opportunity of applying this more recent principle, that it is in the cases with rheumatic pains that it is especially serviceable. He held that until more cases were collected in which this principle of treatment was applied, the question was not ripe for decision. In a single case which had come under his observation in which it was claimed that salicylic acid had been very useful, the sugar had been found increased rather than diminished.

Dr. William H. Draper, the co-referee, said: It is fair to presume that this question would not have been propounded if clinical experience did not suggest it. It certainly is not yet justified by the present state of knowledge in pathology. Although the question is premature from a pathological point of view, it can hardly be regarded as without interest, and possibly importance, from a clinical standpoint. It is from this latter aspect that my remarks shall be made.

By gout is meant, I take it for granted, not simply the arthritic malady, but a diathesis which manifests itself through more or less well-defined derangements of nutrition, which give rise to a variety of secondary cerebro-spinal irritations, and provoke definite structural changes in the blood-vessels, in the connective tissue of the parenchymatous organs, and in the nervous system.

By diabetes we are to understand, I suppose, the more common and lesser form of that disease.

Rheumatism is so vague in its ordinary application that it is not easy to comprehend exactly what is meant in this question. It is presumed that it covers acute articular rheumatism and the subacute forms in which the differential diagnosis from subacute gout is so difficult.

The form of Bright's disease is, probably, the form of chronic diffuse nephritis which is characterized by extreme sclerotic changes in the connective tissues of the kidneys and in the arteries, and by cardiac hypertrophy.

I think that the experience of most clinical observers will justify the statement that gout, rheumatism, diabetes, and chronic Bright's disease are frequently associated, sometimes in the same individual history, more frequently in the histories of families. The association of gout and even chronic rheumatism with chronic Bright's disease is very common in the individual, while the association of gout with diabetes, or of diabetes with granular kidney, is not common. Chronic rheumatism may exist without even being complicated with gout or diabetes, or chronic nephritis, but in families where the association of morbid phenomena can be traced, I think that it will be acknowledged that these diseases are frequently found in more or less marked alliance.

Granting this association, are there any facts to show their correlation? Are they reciprocal, interchangeable affections, transmutations of the same morbid process, and therefore recognizing a common determining cause, as yet unknown?

The first fact that suggests the idea that they are cognate forms is that of heredity. First, as to gout and diabetes. Glycosuria often recognizes a gouty ancestry—the term glycosuria being used to express the lighter form of the disease. In many cases the grave form of diabetes is not traceable to a gouty origin. The speaker had seen many cases leading him to believe that, excluding the cases of diabetes of nervous origin, careful investigation of the family history would reveal the presence of gout in the majority of cases.

Second, concerning gout and rheumatism. The fact of heredity as establishing a connecting link is not so evident. But it has been pointed out that articular rheumatism frequently occurs in the children of gouty parents. The influence of heredity in determining the association of the subacute form of rheumatism and gout cannot be positively decided.

Third, as to the frequent manifestation of heredity in the history of gout and interstitial nephritis, I think that there can be no question. This form of Bright's disease not only occurs as a complication of inherited articular gout, but is often observed in the members of gouty families who have themselves never exhibited any articular lesions. This is especially seen in the female line.

I wish next to call attention to the association with these diseases of certain common derangements of nutrition. While it cannot be claimed that organic chemistry has as yet done more than formulate the general principles that gout and diabetes are associated with the signs of incomplete metamorphosis of the food-elements, it is daily making progress in solving the complex processes by which each atom of carbonaceous and nitrogenous food is finally resolved into carbonic acid and urea. In these two diseases there is a diminished capacity for converting the carbo-hydrates. The occurrence of sugar in the urine of gouty persons, and of lithic acid deposits in the urine of diabetics, is not infrequent.

Gout, diabetes and rheumatism, in their treatment by medicines, exhibit reciprocal relations. In these various affections the alkaline treatment is used with benefit. It is admitted that the value of the alkaline treatment in acute rheumatism is not sufficiently well established to justify the proposition that the disease is on that ground a correlation of gout. The value of salicyl compounds in the treatment of gout, diabetes, and rheumatism suggests the idea that these diseases have something in common, either casual or concomitant, which the preparations of salicin antagonize.

The clinical observations which support the idea of a correlation of gout, diabetes, rheumatism, and certain definite structural changes in the kidneys and blood-vessels, namely, the frequency of hereditary transmission in the same family, and their occasional co-existence in the same individual, the common idiosyncrasy of a diminished capacity for the complete conversion of the carbo-hydrates, and, finally, the common reactions which they exhibit to the same remedies, are of course open to criticism, but they nevertheless excite a reasonable sus-

picion that these diseases have at least certain common features which in all probability proceed from similar derangements of physiological functions.

This much it seems to me may be acknowledged, even in the absence of any adequate pathological evidence that these diseases are attended with any common structural lesions or specific functional disturbances.

There are many unsolved problems in the pathology of gout, diabetes, and rheumatism, and the working hypotheses of the clinical observers in this field are being constantly unsettled by the revelations of the physiological laboratory. It would seem, therefore, that the only conclusion we are at present justified in making as to the correlation of the disease in question is this: Clinically, they are often associated by hereditary transmission, by co-existence and alternation in the same individual, by presenting similar idiosyncrasies in regard to the power of converting the carbo-hydrates, and by being more or less successfully controlled by the same remedies; pathologically, they must still be regarded, in the absence of any demonstrable common determining cause, either functional or structural, as more or less distinct and specific diseases.

Dr. J. T. Dana, of Portland, Me., said that it seemed to him that this discussion might properly have been extended a little, so as to include rheumatoid arthritis. In this affection he thought that the differentiation of it from the other affections has been well made out.

Dr. E. G. Janeway, of New York, remarked that the English people, all through, are gouty. Any rheumatic tendency, except in such individuals, will not hold in other countries. We do not find the same correlation in America. A point which he had noted was, that while members of the Hebrew race are very subject to diabetes, they do not have gout and rheumatism in the same proportion.

With reference to the presence of albumen in the urine of diabetics, in many cases this was to be explained by the irritation of the urinary passages by the saccharine urine.

Dr. A. L. Loomis, of New York, said from a pathological standpoint we could not at present regard these diseases as, directly at least, correlated, but from a clinical standpoint there are many things which make it difficult for us to divest ourselves of the idea that there is a correlation in rheumatism, gout, diabetes, and chronic Bright's disease. These clinical phenomena are often so striking that one comes almost to regard these diseases as different manifestations of the same causes.

There are cases which compel us to take the position that, while in their clinical phenomena they differ very markedly, still in their origin and development they seem to have many things in common; in other words, their correlation seems to be complete.

Dr. H. C. Wood, of Philadelphia, had been led by his experience to conclude that gout and rheumatism were the same thing. He was unable to make the diagnosis between them.

Dr. William Pepper, of Philadelphia, said that the clinical evidences of the correlation of these diseases seemed to him to be so great that we cannot safely disregard it. In considering such common diseases, we must, of course, exclude mere coincidence. He agreed with Dr. Janeway as to the frequency of diabetes in the Jewish race, but he had also found such persons very subject to lithæmia. In all these cases, the importance which a diminution of vital resistance of any particular part plays in the development of the local manifestation must be remembered.

Dr. Dana has referred to rheumatoid arthritis. This appears to be the form in which the nervous element is most marked. All have seen cases in which rheumatoid arthritis has been preceded by influences acting directly upon the nervous system. When we consider the immense amount of nerve-force required in co-ordinating the digestive processes of the stomach, liver, and kidneys, and in superintending the metabolism in the tissues, it seems clear that a depressed condition of the nervous system must play a large part in the production of these affections. In studying cases of these diseases we are usually able to obtain a history of some cause of depression of the nervous system, and this affords a powerful argument in favor of the correlation between these diseases.

The explanation of Dr. Janeway as to the cause of the albuminuria does not hold good in many of these cases. The disappearance of the sugar is not always accompanied by a corresponding decrease in the quantity of albumen.

Dr. A. Jacobi, of New York, said, in regard to the connection between diabetes and gout, that there are several forms of diabetes. The form particularly connected with gout is that due to disturbances of the nutritive processes, particularly that of the liver. This is the form in which the salicylates do good. Their action has seemed to him to be due to the influence of these remedies over the liver, in increasing the quantity of bile and in liquefying it. They are therefore powerful agents in diminishing the tendency to the formation of gall-stones. The forms of glycosuria which come and go are usually benefited by salicylate of sodium. This form of diabetes is generally found in anæmic persons, and not infrequently among women of the Jewish race.

In reference to Bright's disease, this is quite common at the age of forty or fifty, when atheroma of the small arteries appears. At that time gout is also common, and the co-existence of the two does not necessarily indicate a common causation.

Dr. William H. Draper, of New York, in concluding, said that in the cases of rheumatoid arthritis where a reliable history could be obtained he had, as a rule, found evidences of a gouty origin. In regard to gout, he was strongly inclined to believe that the presence of uric acid is only an epi-phenomenon, and that its presence in the joints is not absolutely essential to the occurrence of other true gouty lesions.

In the diabetes of Jews, he had seen the same association of lithæmic conditions as in other races.

He agreed with Dr. Wood in regard to the difficulties of diagnosis. The practitioner cannot always satisfy himself whether he is dealing with gout or rheumatism.

Dr. James T. Whittaker, of Cincinnati, O., read a paper on

SPASM OF THE GLOTTIS IN RICKETS.

The author emphasized the fact that this accident belongs exclusively to rickets, and dwelt upon the value of recognition of this fact, because rickets is, generally speaking, a curable disease, and the spasm of the glottis disappears with the successful treatment of its cause, while treatment addressed to the larynx directly remains without effect.

The speaker next quoted from a number of authorities, to show that this relation between the two affections is not so universally recognized in this country and England as in Germany and France. The two latest authors of text-books in Germany, Strimpell and Sichorst, declare, one that two-thirds, and the other that nine-tenths, of all cases of spasm of the glottis depend upon rickets.

Spasm of the glottis is often the first sign to unmask rickets, for the other evidences of the disease are often attributed to other causes. Thus, general malaise is attributed to dentition, intestinal catarrh to errors in diet, fever and sweating to malaria, bone deformities to premature efforts upon the feet, etc.

Spasm of the larynx indicates the stage rather than the degree of rickets, in that it occurs mostly in cases of rapid advance of the disease, and does not appear in cases of slow progress. So in the spring and fall, when rickets advances in leaps, spasm of the glottis has occurred in epidemic form.

The essayist discussed next the various theories of rick-

ets, which continues to elude investigation to a degree characterized as exasperating. But facts accumulate which go to give it place among the chronic affections. The exemption of hot climates and mountains, Iceland, the Faröe Islands, the complete immunity of Davos, notwithstanding the improper feeding and improper hygiene of sucklings at these places, shows that faults in diet cannot be the cause of it and the symptomatology of it fits better among the chronic affections produced by specific causes.

Spasm of the glottis, in the absence of any constant lesion, falls among the neuroses. The question as to the reflex or direct character of the irritation producing it was decided, after a review of the evidence, in favor of the latter, and since Rosenbach has demonstrated the micro-organism of tetanus, which often begins with and may go no further than trismus, the maintenance of a mycotic theory for the laryngospasm of rickets may be adopted as the best provisional explanation. The mode of onset and character of the accident were next detailed and the symptomatology illustrated with a typical case.

The inefficiency of anæsthetics and all direct means of treatment, as by intubation, tracheotomy, etc., were mentioned next, and douches, flagellations, electricity, cold air, direct appeals to the skin on the first appearance of attack, were described as the best means of combating, and more especially of preventing, the attack. Cod-liver oil, and more especially phosphorus, which may be looked upon almost in the light of a specific, were considered the best means of speedily relieving the rickets, and thus removing the cause of the laryngeal spasm. It has the most favorable prognosis of all kinds of laryngospasm, as Monte lost but 8 of 329 cases.

Dr. Edward T. Bruen, of Philadelphia, read a paper entitled

NOTES ON SOME CASES OF DIAPHRAGMATIC PLEURISY.

Dr. Bruen said that the object of his paper was to briefly state the diagnostic features of diaphragmatic pleurisy. He did not attempt a review of the interesting historical literature of the disease. He admitted that the diagnosis of this affection was often only established at the post-mortem table, since the process is often latent and frequently possessed few distinctive physical signs. Primary pleurisy of this part of the pleura he considered rare. It is oftener a complication attendant upon acute inflammatory processes in the adjacent pulmonary lobes, the costo-parietal pleura, or in the liver or peritoneum. Under the foregoing conditions, invasion of the diaphragmatic pleura may be characterized by special symptoms which may entitle one to designate this class of cases as acute inflammation of the diaphragmatic pleura.

Inflammation of this portion of the pleura may be a subacute or chronic process, developed in consequence of contiguous subacute or chronic inflammation or malignant growths. In such cases, the process in the diaphragmatic pleura may become specialized by symptoms which should lead the clinician to differentiate the diaphragmatic pleurisy from the associated pathological changes.

In the acute form of this disease many of the more prominent and differential symptoms may be masked by the greater importance of the primary disease.

The symptoms of diaphragmatic pleurisy may also be masked if the liver be enlarged or the intestines distended with gas, for these conditions may sensibly modify the freedom of the diaphragmatic movements.

The terminations of the acute cases are intertwined with the associated pathological processes, and the gravity of the case is not necessarily increased if the symptom of hiccough is subordinate, the latter being an exceptionally uncontrollable and exhausting symptom. In primary cases a favorable issue may occur.

To show that the diaphragmatic pleurisy may progress to a marked degree without the manifestation of diagnostic symptoms, the case of a negro man was related in whom post-mortem examination showed lesions of general miliary tuberculosis, with marked thickening of the diaphragmatic pleura. It was shown in this case that the peritoneum was infected through the connecting channel of lymphatics between the pleura and peritoneum. During life some friction-râles were heard along the upper border of the fifth rib and near the margin of the seventh in the axillary line, although a large amount of fluid was contained in the chest. The autopsy showed that the lung, rendered rigid and thick by the tubercular infiltration, projected as a rigid mass into the pleural space, displacing the fluid, and then the separation of flakes of exudation doubtless produced the râles. It was stated that in the subacute or chronic cases the special symptoms of diaphragmatic pleurisy were more conspicuous than in many of the acute forms of the disease.

Illustrative cases were cited, one occurring in the Philadelphia Hospital, secondary to induration of the right apex and general emphysema, in which the disease was correctly diagnosticated, as the post-mortem examination showed.

The diagnosis of a disease in which there is often so little that is distinctive, must necessarily be a difficult problem. It was shown by the relation of several post-mortem examinations that the process can exist in advanced form, on one side of the diaphragm at least, without special symptoms. If the diaphragmatic pleurisy should complicate any form of pulmonary or hepatic pathological process, or circumscribed peritonitis of the superior part of the abdominal cavity, one may note that the subjective sense of respiratory distress and the objective symptoms are disproportionate to those conditions, and therefore the possibility of the existence of diaphragmatic pleurisy should be considered.

The more important diagnostic symptoms which, if present, should direct attention to the possibility of diaphragmatic pleurisy, are, in the order of their frequency and importance, as follows: Subjective sensation of pain over the zone which borders the diaphragmatic plane, pain at the point described by Dr. Mussey, viz., one or two fingers'-breadth from the middle line on a level with the tenth rib, or at the intersection of a line drawn from the osseous part of the tenth rib and one drawn along the sternum. The pains may be constant, yet also paroxysmal or provoked by pressure, or by increased respiratory motion, by irritation of the diaphragm, swallowing or vomiting, or by the pressure of the distended abdominal viscera. Radiating pains around the chest and upper abdominal zone may occur. Fixation of the diaphragm is an equally important symptom. There will usually be feeble or absent respiratory murmur near the diaphragmatic zone. Dry or moist friction râles may be audible along the converse surface of the diaphragmatic pleura. The percussion resonance may be dull when there is much exudation, but more commonly it is tympanitic, since the partial paresis of the diaphragmatic muscle permits the pressure of the abdominal viscera to raise it somewhat above its usual area. In certain cases the posture of the patient may be bent forward with hypochondriac retraction and epigastric hollowness, but the dorsal decubitus is very often maintained. The respiration is quickened in a few cases, so that there may be dyspnœa or orthopnœa, but these symptoms may be almost entirely absent in subacute or chronic cases on account of the compensatory costal respiration. Cough is a variable symptom, and the same may be said of hiccough; both are often absent. Finally, in the writer's experience, diaphragmatic pleurisy has been chiefly a thickening with adhesions, rather than accompanied with much fluid effusion. Hence the importance of noticing the foregoing symptoms, since the presence of much fluid effusion would be more obvious by means of percussion, auscultation, and other physical signs.

The prognosis was stated to be intertwined with the

intercurrent pathological processes, and the power of adaptation possessed by the pulmonary system is so great that the duration, even of diaphragmatic pleurisy, may be indefinite.

DEMONSTRATION OF BACTERIAL CULTURES FROM A CASE OF MYCOTIC ENDOCARDITIS IN MAN,

and of Specimens showing the Experimental Production of the Disease in Rabbits, by DR. T. MITCHELL PRUDDEN, of New York.

The communication was a preliminary one, the experiments not having yet been completed. For some years the presence of bacteria has occasionally been observed in the cardiac and peripheral lesions of malignant ulcerative endocarditis. It has, however, been found that, not only not all cases of acute vegetative endocarditis, but not even all cases of ulcerative endocarditis, present bacteria in their lesions. The speaker thought that the anatomical distinction was not clearly enough drawn between simple and malignant ulcerative endocarditis. Of eleven cases of well-marked ulceration of the valves which he had studied within the past four years only four showed the presence of bacteria.

In only one case of malignant ulcerative endocarditis was he able to isolate and study the living bacteria. This was a case of pyæmia following cuneiform osteotomy for club-foot. The tests applied showed the bacterium to be the staphylococcus pyogenus aureus.

The experiments on animals were then described, and the following conclusions were drawn: If we sum up the results of combined morphological and biological examination of the cases thus far studied, we find that the sphero-bacteria found in the cardiac and peripheral lesions were the stryphococcus pyogenus and the staphylococcus pyogenus aureus and albus, either alone or together. The intravenous injection of either of these, or a mixture of them, into the rabbit, after mechanical or chemical injury of the endocardium, is capable of inducing lesions strictly analogous, if not identical, with those found in malignant ulcerative endocarditis in man. The coccus sepsis of nicolain is capable of producing similar results. Neither the endocardial injury nor the intravenous injection of bacteria alone are sufficient to induce the cardiac lesion. Both are necessary. As far as the observations go, they tend to confirm the view that malignant ulcerative endocarditis is simply one of the forms of pyæmic lesion determined by the predisposing conditions of the endocardium. Whether or not there are other forms of the disease induced by other species of bacteria, or having no relation to bacteria at all, are questions which are more likely to be settled by experiment than by conjecture.

Adjourned.

FRIDAY, JUNE 11TH—SECOND DAY—MORNING SESSION.

The first paper was by DR. W. T. COUNCILMAN, of Baltimore, on

CERTAIN ELEMENTS FOUND IN THE BLOOD OF MALARIAL FEVER.

It has long been known that changes in the blood occur in this disease. It is now known that in the red corpuscles there are certain bodies which appear to be living organisms, and these occur only in this disease. These are found by taking a drop of blood and spreading it on a slide, so that there shall be but a single layer of corpuscles. These are stained with a weak solution of fuchsin. The nuclei of the white corpuscles will be intensely stained, the red slightly stained, and in some of the red corpuscles will be seen brightly stained bodies of irregular shape. These exhibit distinct amœboid movements. The variety of their changes of form was illustrated by drawings. Certain hyaline bodies are also found, and were described. The speaker then referred to the work of other investigators in this field, and gave a review of the results which they had obtained.

TETANY,

was the title of a paper by DR. H. M. LYMAN, of Chicago.

Tetany may be defined as a more or less generalized intermittent, usually tonic convulsion of the muscles of the limbs and trunk; sometimes involving the face and visceral organs, usually painful, but never attended with loss of consciousness. The disorder is functional, and is based upon no distinctive pathological lesions of the central nervous organs. It is manifested in a series of attacks which occur at intervals, varying in length from a few hours to weeks or even months. During the paroxysms the flexor muscles are usually the seat of contracture, but sometimes the extensor muscles of the limb are principally involved. Single muscles alone may be attacked. These contractions may be very energetically developed, with considerable pain, or they may be sluggish and painless. The pain is usually due to the muscular spasm, but neuralgia may be associated with the cramp, and the skin may sometimes become inordinately sensitive. The pain may at other times become located about the joints, which then present the characteristic appearance of rheumatism. Diminished sensibility in certain parts of the body may be sometimes observed during or after an attack. The special senses are rarely disturbed. The action of the heart is seldom changed, except by transient palpitations.

The disease is rarely fatal, although death has occasionally resulted from prolonged spasm of the respiratory muscles. The duration of the disorder is quite variable and relapses are rather frequent.

Having no relation with any particular lesion of the nervous centres, tetany appears to be dependent upon a functional instability of the nervous and muscular organs.

The treatment must be directed in a general way against the fundamental instability of the individual constitution. Mild attacks require no special therapy, but severe attacks often demand the energetic use of narcotics and anæsthetics for their relief.

DR. REGINALD H. FITZ, of Boston, read a paper on

PERFORATING INFLAMMATION OF THE VERMIFORM APPENDIX; WITH SPECIAL REFERENCE TO ITS EARLY DIAGNOSIS AND TREATMENT.

The paper was based upon an analysis of two hundred and fifty-seven cases of unquestionable perforating ulcer of the appendix, and of two hundred and nine cases diagnosticated as typhlitis, perityphlitis and perityphlitic abscess. In the latter series the diagnosis was clinical, not anatomical.

The important features in the etiology of appendicitis were considered, also the limitations as to sex and age. It was found that the disease occurred most frequently among previously healthy youths and young adults, especially males; that a fecal concretion or foreign body was present as a local cause in more than three-fifths of the cases. Attacks of indigestion and acts of violence, especially when indirect, were exciting causes in one-fifth of the cases. The action of these causes was favored by a constipated habit or by congenital or acquired irregularities in the position and attachment of the appendix.

The first characteristic symptom of a perforating appendicitis was found to be a sudden severe abdominal pain, usually in the right iliac fossa, where tenderness could always be found, even when the pain was referred to some other locality. The pain was attributed to the actual perforation or the detachment of fresh adhesions.

Fever was the next characteristic symptom, and occurred in the course of twenty-four hours. Finally came the swelling, which made its appearance in the course of three days.

The chief source of danger from the appendicular peri-

tonitis arose from its becoming generalized. Such a result followed most frequently between the second and fourth days. More than two-thirds of the patients died during the first eight days, and two-thirds of these between the fourth and eighth days inclusive.

The reader recommended at the outset the opium treatment, with rest and a liquid diet, the food being given in small quantities, frequently repeated. If it became evident that general peritonitis was imminent at the end of twenty-four hours after the sudden intense pain, the appendix should be exposed and removed. Usually the symptoms were not so urgent that the appearance of the swelling could not be awaited. Although Willard Parker advised that the abscess might be opened as early as the fifth day, the practice has been to operate at a later date. Forty-seven per cent. of the cases were operated upon in the second week, and twenty-six per cent. after the third week.

More favorable results in the future were to follow the earliest possible opening of the swelling. This, in most instances, was at the outset a sac formed by a circumscribed peritonitis. It was usually present on the third day of the disease, dating from the pain, its first marked characteristic symptom. Negative results from a diagnostic puncture did not contraindicate the operation.

Dr. William Pepper had been led by his experience to believe that perforation of the appendix is only the explosion of an old catarrhal appendicitis, and that it is not an acute idiopathic affection.

The diagnosis in these cases is a matter of great difficulty in the early days, except where it is associated with considerable pericæcal inflammation.

He agreed with Dr. Fitz that early operation gives the only chance of saving the patient; the third day is not too soon. The difficulty is to arrive at a sufficiently clear diagnosis at that early date to justify laparotomy as an exploratory operation.

Dr. J. T. Dana, of Portland, Me., thought that it was not rare to find inflammation of the appendix as a latent affection. In a case which he had recently seen the first symptom was the occurrence of general peritonitis. The case resulted fatally in seventy-two hours. At the autopsy general peritonitis was found, and there was an opening in the appendix through which a concretion had escaped. A second was found within the appendix. There had been no previous symptoms to call attention to disease of the appendix.

Dr. A. L. Loomis, of New York, remarked that this was a positive paper, and it gives us some positive data on which to base our modes of action in this condition. He thought that it was impossible, in the majority of cases, to make an early diagnosis by the ordinary means. Of the symptoms given by the patient the most certain indication seems to be given by the occurrence of a chill. When pain is marked it will usually be localized in the left side, but not necessarily. Recognizing the importance of the early diagnosis, he decided, some years ago, to put the patient under the influence of an anæsthetic, and examine by the rectum and externally. The patient died. In three cases he had made the diagnosis by this plan. It must be remembered that the vermiform appendix does not occupy the same position in all individuals.

As soon as the diagnosis of perforation is made out the operation should be performed.

Dr. E. G. Janeway, of New York, divided these cases of appendix disease into three classes. In one an inflammatory process of the cellular tissue, with or without the formation of pus, is established. This may go on to recovery. If pus forms, surgical procedures should be resorted to. In another class of cases there is a circumscribed collection of pus in the peritoneal cavity. In this class operation should be resorted to as soon as the presence of pus is determined. In the third type we have, as a result of the perforation of the appendix, general peritonitis. The pain and tenderness in these conditions are not always on the right side. As has been said, the position of the appendix is not constant.

In these cases you can generally find, on careful examination in the region of the cæcum, at some point, a feeling of deep-seated induration, and at this point there is tenderness.

The Association then went into executive session.

The officers elected for the ensuing year are as follows:

President—Dr. S. Weir Mitchell, of Philadelphia.

First Vice-President—Dr. Francis Minot, of Boston.

Second Vice-President—Dr. R. Palmer Howard, of Montreal.

Secretary—Dr. George L. Peabody, of New York.

Recorder—Dr. James T. Whittaker, of Cincinnati.

Treasurer—Dr. W. W. Johnson, of Washington.

Council—Dr. William H. Draper, of New York; Dr. Robert T. Edes, of Boston; Dr. H. M. Lyman, of Chicago; Dr. Samuel C. Busey, of Washington; Dr. Frederick C. Shattuck, of Boston; Dr. William Osler, of Philadelphia, and Dr. W. W. Welch, of Baltimore.

The proposition with reference to the formation of the Association of American Physicians and Surgeons was presented and approved. The following committee was appointed to confer with other organizations: Drs. William Pepper, of Philadelphia; Robert T. Edes, of Boston; R. P. Howard, of Montreal; James T. Whittaker, of Cincinnati, and Francis Delafield, of New York.

Adjourned.

Afternoon Session.

Dr. William M. Polk, of New York, read a paper on

PELVI-PERITONEAL INFLAMMATION,

which will appear in a future number of The Record.

AN EXPERIMENTAL STUDY OF ACUTE GLOMERULO-NEPHRITIS,

was the title of a paper by Dr. W. H. Welch, of Baltimore.

The questions which have not as yet received full and satisfactory answers are: What is the origin of the cells which often in nephritis occupy the space between the glomeruli and the capsule of Bowman? Does migration of the white corpuscles or diapedesis of the red corpuscles take place through the glomerular capillaries? What relation, as to frequency and intensity, do changes in the glomeruli play in the pathology of Bright's disease? In expectation that light might be thrown upon these questions the speaker had experimented on rabbits and white mice, by the production of acute cantharidal poison.

Microscopical examination of the kidney in the rabbit shows here and there foci of infiltration, with small round cells, doubtless migrated white blood-corpuscles. The epithelium of the convoluted tubes is in places normal in appearance; in other places it is swollen, and often the inner part of the cells is broken off, appearing as a granular mass in the lumen of the tube. The most marked change is found in the Malpighian bodies. In the greater number of these there is between the glomerulus and Bowman's capsule a wide space, partly or wholly filled with cells. These are larger than white blood-corpuscles. They are frequently arranged in a crescentic mass. These appearances are similar to those described in glomerulo-nephritis in man. In the latter case these cells are attributed to the swelling and desquamation of either the capsular or glomerular epithelium. Such explanation does not hold in the present case. There are no appearances which justify the derivation of the greater number of the cells from the epithelium of the glomerulus. These cells cannot be regarded as white blood-corpuscles changed by the action of the poison, for the cells circulating in the blood are exposed to the same poison. These cells may be derived from

the epithelium of the convoluted tubes in immediate communication with the Malpighian bodies. The cells in the capsular space are identical with those in the convoluted tubes. At times there can be found groups of cells arranged in the form of a ring, with a central space just like the epithelium of the uriniferous tubules.

Swelling of the endothelium and accumulation of cells in the glomerular capillaries appears to be a nearly constant lesion in the acute nephritis of scarlet fever. In one case examined this was almost the only lesion in the kidney. Occasionally pathologists meet with kidneys in which the apparent changes do not explain the symptoms. In such cases careful examination of the glomerular capillaries should be made. It is difficult to think of any lesion of the kidney more destructive to its function than occlusion of the capillaries.

While disposed to attach much importance to the changes in the glomerular capillaries, we are not justified in asserting that these changes constitute the primary and essential cause of Bright's disease. They are co-ordinate with other lesions.

Dr. William Osler, of Philadelphia, read a paper entitled

BICUSPID CONDITION OF THE SEMILUNAR VALVES AND ITS RELATION TO AORTIC DISEASE.

A bicuspid condition may be said to exist when two of the three sigmoid cusps have more or less perfectly fused, so that the arterial orifice is guarded by only two segments. The abnormality is a well-recognized one. Dilga recently collected the statistics; and has found sixty-four cases of this condition in the pulmonary artery, and twenty-three in the aorta. This statement gives an incorrect idea of its frequency in the latter vessel. In over eight hundred autopsies at the Montreal General Hospital, there were eighteen cases, seventeen in the aortic valves alone, and in one pulmonary and aortic segments were both involved.

With the exception of one case, a fœtus at the eighth month, the patients were adults. The ages ranged from twenty to sixty years. This contrasts in a marked manner with the history of this defect in the pulmonary artery. A great majority of the instances present other serious anomalies of development, and death takes place before puberty. Unquestionably the majority of the cases are congenital, and result either from faulty development or fœtal endocarditis. The former view seems the more probable.

Dr. George M. Sternberg, U. S. A., read a paper on

THE BACILLUS OF TYPHOID FEVER.

Recent researches support the view that the bacillus described by Eberth in 1880 bears an etiological relation to enteric fever, although the final proof that such is the case is still wanting. This proof would consist in the production in one of the lower animals of the specific morbid phenomena which characterize the disease as it occurs in man, by inoculation of a pure culture of the bacillus. Thus far we have no evidence that any one of the lower animals is subject to the disease as it occurs in man; but Fraenkel and Simmons have shown that the bacillus of Eberth is a pathogenic organism, and that pure cultures injected into the peritoneal cavity of mice, or into the circulation of rabbits, causes the death of these animals, and that colonies of the bacillus are found in the spleen, which resemble in every respect the colonies found in the spleen and other organs of typhoid cases.

The researches of Eberth, Meyer, Gaffky, Fraenkel, and others, indicate that this bacillus is constantly present in the intestinal glands and in the spleen of typhoid cases, and Gaffky has shown that pure cultures may be obtained from the spleen even in cases in which a microscopical examination fails to demonstrate the presence of the characteristic colonies.

The researches of Brieger show that a toxic ptomaine is produced as a result of the vital activity of Eberth's bacillus, when it is cultivated in albuminous culture media. This injected into guinea-pigs, causes salivation, diarrhœal discharges, debility, dilated pupils, rapid respiration, and death at the end of twenty-four or forty-eight hours.

Demonstrated facts relating to the propagation of typhoid fever indicate that it is due to an organism which is capable of multiplication external to the human body, in a variety of organic media at comparatively low temperatures. Eberth's bacillus complies with these conditions. In consideration, therefore, of its constant presence, and the absence of any other organism, as shown by microscopical examination and culture experiments, the inference seems justifiable, in the recent state of science, that this bacillus bears an etiological relation to the disease in question.

Dr. E. C. Seguin, of New York, gave

A CLINICAL REPORT OF NINE CASES OF HEMIANOPSIA.

He presented an abstract of nine cases of lateral hemianopsia due to cerebral lesion, and called attention to the following points of the nine cases: Five had right lateral hemianopsia, and four left lateral hemianopsia. Three of the cases of right-sided hemianopsia presented the following association of symptoms: Hemianopsia, right-sided hemiparesis with post-paralytic ataxia and partial hemianæsthesia. Two of these cases also exhibited alexia without other aphasic symptoms. It is interesting to note that all cases of right-sided hemianopsia do not have ataxia, and also that post-paralytic ataxia is not always accompanied by hemianopsia, though probably this is more common than is generally supposed. The six other cases were practically cases of pure hemianopsia, *i.e.*, there were no paralytic or sensory symptoms or aphasia indicating extensive cerebral disease.

In the first category the lesion is probably placed on the outer edge of the thalamus, so as to involve the fasciculus opticus and the posterior division of the internal capsule. In the second category the lesion is quite certainly farther back, or in the white matter of the occipital lobes. In two cases of the second category marked and increasing weakness of both legs was present—a symptom perhaps due to the upward and forward extension of a tumor toward the paracentral lobule. A very peculiar symptom in two cases of the second category, and one which the author thinks is new, was the occurrence of hallucinatory images for a short time in the darkened half-field. This is a symptom of irritation, and analogous to the convulsive movements which sometimes precede paralysis of a limb when its motor centre is being destroyed by disease.

A very puzzling point is the perfection of central vision in these and other cases of central hemianopsia. The vertical line always passes by the point of fixation, no matter on which side the blindness is. We must conclude that the macula is not involved in the loss of function, and the question arises can the macula have a double enervation from the visual centre? This point the author intends to study thoroughly.

The speaker also exhibited specimens illustrating the seat of lesion in certain cases of hemianopsia.

Dr. Henry Formad exhibited specimens of kidneys demonstrating some peculiarities of cyanotic induration of those organs. This condition is produced by anything which interferes with the circulation through the kidneys. The shape of the kidney where the cyanotic induration results from the use of alcohol is rounded and shortened. The kidney presents a pig-back appearance. Where the cyanotic induration results from heart disease the shape of the organ is not altered, as the condition takes place gradually.

The following papers were read by title: "Notes of a Case of Hepatico-Bronchial Fistula," by Dr. J. E. Graham, Toronto; "Pancreatic Hemorrhage as a Cause of Sudden Death," by Dr. F. W. Draper, of Boston; "Pernicious Anæmia," by Dr. A. Jacobi, of New York; "A

Case of Hodgkin's Disease," by Dr. F. Forsheimer, of Cincinnati.

A vote of thanks was tendered the Government officials and the profession of Washington for courtesies extended.

Adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 17, 1886.

CHARLES CARROLL LEE, M.D., VICE PRESIDENT, IN THE CHAIR.

DR. A. B. JUDSON, Statistical Secretary, announced the death of

HORACE PUTNAM FARNHAM, M.D.

DR. W. M. POLK then read a paper (see p. 1) on

ALEXANDER'S OPERATION, AND ITS APPLICATION TO UTERINE DISPLACEMENTS.

The discussion was opened by DR. J. B. HUNTER, who regarded the operation as one yet on trial, and concerning which argument was not of much avail unless it could be supplemented by clinical experience, such as had been given by Dr. Polk. He thought there was no question that the operation had a future, and that there were certain cases in which it was a suitable one to perform. To say that it was suitable in only certain cases was only to say that which was true of every operation.

The real question was, whether it gave any advantage over other methods of treatment. He had operated in three cases, and had had opportunity to examine the patients very recently, and had found the uterus firmly "moored behind the symphysis pubis," as Dr. Alexander had expressed it. Dr. Hunter agreed with Dr. Polk as to the cases in which it was advisable; that is, where the uterus was prolapsed, and where it was uncertain whether by the perineal operation it could be kept in position. He thought no one would attempt to perform the operation where adhesions to any considerable extent were present. It seemed to him that in those cases in which the uterus was retroverted with prolapsus of the ovaries, and where no form of pessary could be tolerated, the operation gave a certain amount of advantage over any other procedure which could be resorted to. He thought, however, that there was a certain amount of risk of the occurrence of peritonitis. Three cases of death had been reported, one occurring in this city, but he thought that with careful antiseptic precautions the operation could be regarded as a reasonably safe one. He also regarded it as no more dangerous than the operation for lacerated cervix, and that it was no more difficult to perform. In one of his cases the ligament was so small that he could not at first believe that it would answer for the purposes of traction. But as it was drawn out it grew larger and larger, and proved to be abundantly firm to moor the uterus. He had found less trouble, so far as finding the ligament was concerned, in cases in which there was a large amount of fat than in lean patients. As to whether the operation was efficacious, time would be required to form any intelligent opinion. One year, at least, must elapse before it could be decided whether or not the operation had been successful. He had made it a point to keep the patient in bed four weeks and to use a pessary. He preferred the use of the bone drainage-tube. In all of his cases union has taken place rapidly. He believed that in all suitable cases where other means did not offer good prospect of cure that the operation was advisable, and he should continue to perform it until he was satisfied of its value or the reverse.

DR. W. T. LUSK said that he had had but little experience in the performance of this operation. So far he had been an observer chiefly, with the additional fact that at first he was somewhat sceptical concerning the advisability of the operation, but at the same time not so prejudiced but that he could be convinced of its utility. He had been favored by Dr. Polk with the opportunity of seeing several of his operations, and had watched the cases with a great deal of interest. He only arose to say that he had been completely converted to the operation, and he believed that it was destined to do a great deal of good to *working-women*. He regarded it as an operation only moderately difficult to perform, and that ordinary anatomical knowledge should serve one in attempting it. With proper precautions the operation should not be attended with any danger. True, there had been serious cases, but it had seemed to him that the accidents which had followed the operation should have been avoided. The operation was not extremely difficult; it was reasonably safe, and the dangers which had followed were not inherent in the operation itself. The question then arose, Was it necessary? Dr. Lusk's answer to this question was that pessaries would not enable us to get all the results desirable in the class of cases to which the operation was applicable, and that these results might be obtained by the operation. Pessaries might be well enough for the rich, who could have housekeepers, nurses, and carriages, but they were not sufficient for the successful treatment of women belonging to the working class. If relief could not be afforded to the latter class of patients, they were in a sad condition indeed, and many of them were so afflicted that they went from one hospital to another, or went home, and, being unable to perform their household duties, became the subjects of the abuse which so frequently occurred among the lower classes. If any operation could be devised which would place these unfortunate women on a level approximating that of their more fortunate sisters, it was of immense importance, and it seemed to him that Alexander's operation would relieve a great many of them, and he should hereafter attempt to give the benefit of the operation to those poor women.

There was one point which it was difficult to decide, and that was the result of the operation on pregnancy. That is to say, was it not possible to so shorten the ligaments as to draw the uterus forward to such an extent as would interfere with the patient passing safely through her confinement? Dr. Alexander had reported two cases in which the women had passed through pregnancy and labor safely after his operation had been performed; but more cases were needed to enable us to decide this point.

DR. H. J. BOLDT had not had any experience in the performance of the operation upon the living subject, but he had encountered some difficulty in securing the round ligaments when operating upon the cadaver. From his experience simply in operating upon the dead subject he thought it important to make traction sufficient to bring the uterus into its normal position rather than to rely upon the sound in the uterus for that purpose. Although Dr. Alexander had reported cases in which women had done well during labor after the performance of his operation, Dr. Boldt regarded the effect which the position of the uterus might have upon labor as an important question.

DR. LEE had operated in three cases in private practice. All the operations had been performed within the last eighteen months, and all the patients belonged to the middle class. The results had ultimately been good, although in one an abscess formed which gave him a good deal of trouble. In another case he had to resort, after the first week, to the use of a pessary. But in all three patients the uterus had remained in place up to within one month or six weeks.

With reference to the causes which led to the performance of the operation, there was no procidentia in either case. In each instance there was simply an incomplete retroversion or retroflexion without adhesion, attended with such a degree of tenderness that a pessary could not be tolerated, and there was no difficulty attending the performance of the operation. He certainly thought, in common with Dr. Hunter and Dr. Lusk, that the opera-

tion had a great future in the class of cases described and limited by Dr. Polk in his paper.

Dr. Polk, in closing the discussion, referred to a note which he had received from Dr. Jacobus, who had examined one of the women upon whom he had operated, and had reported to him that the uterus was in as bad a position as it was before the operation. Dr. Polk said it was very evident that the patient to whom Dr. Jacobus referred was one in whom he found adhesions, and to whom he had already referred in his paper. It was one case in which the result had not been so favorable as could be desired, but he did not pretend to say that, in every case, Alexander's operation would be successful. He only claimed that in the majority of instances it would succeed.

The Academy then adjourned.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 19 to June 26, 1886.

Perin, Glover, Colonel and Assistant Surgeon-General. Granted leave of absence for one month, with permission to apply for one month extension. S. O. 54, Department of Dakota, June 14, 1886.

Brooks, John, Major and Surgeon. Ordered for duty as Post Surgeon, Fort McHenry, Baltimore, Md. S. O. 67, Division of the Atlantic, June 23, 1886.

Dewitt, Calvin, Major and Surgeon. Ordered for duty in Department of Dakota. S. O. 142, A. G. O., June 21, 1886.

Gardiner, John de B. W., Captain and Assistant Surgeon. Ordered for duty as Post Surgeon, Newport Barracks, Newport, Ky. S. O. 67, Division of the Atlantic, June 23, 1886.

Gibson, Robert J., Captain and Assistant Surgeon. Granted leave of absence for thirty-five days. S. O. 43, Division of the Pacific, June 14, 1886.

Official List of Changes in the Medical Corps of the United States Navy during the week ending June 26, 1886.

Beardsley, Grove S., Medical Inspector. Detached from the Navy Yard, Norfolk, and ordered to the Brooklyn.

Bright, G. A., Surgeon. Detached from the Brooklyn and ordered to Navy Yard, Norfolk.

The Ethics of Journalism.—A medical journal of Paris has issued a circular, addressed to physicians practising at various watering-places in France, in which it offers, for a consideration of one hundred francs, to insert their names each week during the season in a special department entitled: "Thermal Stations of France, Season of 1886." The names of those physicians only who pay the fee will be printed in connection with the description of their special stations. A number of the other Parisian journals have united in a public protest against this action on the part of their esteemed contemporary.

Discontinuance of a Journal.—With the issue of April 3, 1886, the *Revue Médicale* has suspended publication. This action was caused by the death of the editor, Dr. Edouard Fournier, the family not wishing the publication to continue under other hands. Dr. Fournier left two sons, and the hope is expressed that they will, in a short time, resume the pen laid down by their father.

The Question of Operation in Congenital Torticollis.—Dr. B. E. Hadra, of Austin, Tex., sends a reply to the criticism made by Dr. Brooks upon his article on "Congenital Torticollis." He says that when speaking of cicatricial tissue, and then of fibrous degeneration, he claims to be in accord with the present teaching, which regards the former as a certain stage of the latter; and that by degeneration of muscle he means an increase in the fibrous tissue at the expense of the muscular fibres which become atrophied. He does not deny that there are cases of congenital torticollis which may be cured without cutting, but maintains that there are some which demand the knife, and quotes Bouchut that "myotomy is indicated, though orthopædic treatment will often suffice, but the former is preferable, and always surer in results." Dr. Hadra continues: "Dr. Brooks further tries to frighten the surgeon by the dangers of such operations, and advises them to operate rather on a six-months child than on a six-weeks-old baby. But surgeons know that there is no danger in such operations, and that it makes no difference whatever whether the child be six months or six weeks old. Still, being of a pacific temperament, I am willing to compromise. I am willing to concede that waiting for a reasonable time would be good policy, if, otherwise, circumstances allow it, because we might not be able to make out positively the nature of such cases. In that I am yielding to the aggressive doctor, though I am satisfied that cases like mine will never get well without the use of the knife. I have seen some cases of torticollis in later life, and they were of such nature, and should have been operated upon in early infancy. For illustration, I have now in mind the case of a thirteen-year-old boy who was born with torticollis, as the parents testify, and who is disfigured yet, in spite of a protracted emollient and orthopædic treatment. In conclusion, I would state that there was an error in my article (January 23d, page 91), the word 'not' having been misplaced. The sentence should read: 'That the fibrous degeneration was *not* limited to the point of rupture, but extended over the whole,' etc."

Chorea of the Larynx.—Professor P. Masucci, after describing two cases of this affection, recently observed by him, writes of the two theories at the present time in vogue to explain its occurrence. Massei thinks that chorea of the larynx is due to increased reflex sensibility of the larynx, while Schrötter looks upon it as a pure neurosis. The latter opinion is shared by most authorities. As regards the treatment, the author obtained rapid and permanent results from the use of the galvanic current alone. In this strange affection many remedies have been found efficacious at one time and utterly useless at another, so that it is impossible to decide upon the precise pathogenesis from the results of treatment.—*Rivista Clinica dell' Università di Napoli*, April, 1886.

TWO CASES OF MYXŒDEMA, WITH REMARKS ON THE PATHOLOGY OF THE DISEASE.

BY A. BRAYTON BALL, M.D.,

[HOSPITAL TO CURE DISEASES OF THE THROAT AND LUNGS.]

So few cases of this remarkable affection have been reported in this country (I have collected reports of only eleven[1]) that the following two cases, occurring in my own practice, may not be without interest. The first has been under observation for twelve years, the other for only the past eight months.

Mrs. B——, married, aged forty-eight, Jewess. Her father died in 1880, aged seventy-three, of myxœdema of more than ten years duration, terminating in cardiac and Bright's disease. Dr. Schwedler, of this city, his family physician, informs me that the symptoms were of a typical myxœdematous character. An older sister of my patient also died of myxœdema in 1884, aged fifty-two, with renal symptoms. Dr. Mark Blumenthal, her physician, informs me that in her case the disease ran a comparatively rapid course. Five years before her death she had a small goitre, which disappeared within a few months, and was soon followed by well-marked myxœdema. Albumen was not found in the urine until eighteen months before her death; then serious œdema of the lower limbs developed, with ascites, accompanied by a certain amount of relief from the myxœdematous symptoms, as has often been noticed in other cases of this disease when serious effusions take place. In my patient also, Mrs. B——, there is a history of preceding goitre following the birth of her first child, in 1860. Under treatment the tumor subsided within a few months. Between 1860 and 1871 she gave birth to seven children. In 1873 her menstruation ceased, and remained absent for three years, then returned at irregular intervals for eighteen months, and disappeared finally in 1877, at the age of thirty-seven. In 1879—menstruation having ceased entirely for nearly three years—she became pregnant, and was delivered of a healthy child after an easy labor, and without subsequent complications. In 1873, without assignable cause, except perhaps the rapidly recurring pregnancies, she became very anæmic. She came under my care in 1874, and from that time until 1881 was regarded as a puzzling case of obstinate anæmia. The development of myxœdematous symptoms was very gradual; the order of development being first general anæmia, then solid infiltration of the skin, followed by sluggishness of bodily movements and mental functions. Her present condition is as follows:

The face has a cretinoid appearance. It is enlarged in all dimensions, especially in its transverse diameter. The cretinoid effect is enhanced by the apparently small size of the forehead, where the skin is less swollen. On the cheek and rest of the face the skin is waxy and translucent. Each cheek presents a bright pink flush, sharply defined and bounded above by the inferior border of the lower eyelids. Friction increases the size of the patch, and renders it more vivid. The eyelids, especially the lower, are swollen, baggy, and wrinkled transversely. The palpebral fissure is diminished in size; the eyes consequently appear small and farther apart than is normal. The nose is thickened and broadened; the lips swollen, especially the lower one, which is pendulous, everted, and of a violet hue. The mouth is widened. There is an excessive flow of saliva, especially at night upon the pillow, but this symptom is less marked now than formerly. The tumefaction and stiffness of the face obliterate its natural curves and lines, and give it an expressionless, mask-like appearance. On the body and limbs the skin is everywhere swollen, harsh, scaly, and does not pit on pressure, except on the lower part of the legs, where there is some serous œdema. The hands are thickened, broadened, "spade-like;" the nails brittle and incurvated. At times a rapid increase of the cutaneous œdema takes place, producing an uncomfortable sensation of being hide-bound, and accompanied by a marked diminution in the amount of urine. After a few days profuse discharge of pale urine occur and the body perceptibly diminishes in size, with relief to the feeling of tension. For the past year these attacks have recurred less frequently.

On each side of the neck, in the posterior triangles, are bolsters of fat, such as are found in sporadic cretinism, and as were regarded by Hilton Fagge as a constant accompaniment of that disease. At the back of the neck is a considerable deposit of fat, but no definite tumor; large deposits are present also on the breasts and abdomen, the latter especially. The hair on the scalp is scanty, dry, brittle; the eyebrows have almost disappeared, and there is no hair on the axillæ or pubes. During the past year there has been a slight growth of new hair on the scalp, a point of some interest in connection with a diminution of the swelling of the hands during the same period, as showing that the mucinoid stage of the disease is probably now declining. Two congenital moles on the face have grown considerably within the past few years; on the outer aspect of the right forearm are several deeply pigmented moles of recent appearance. The skin of the forehead presents a brownish-yellow discoloration, resembling the pigmentation seen in Addison's disease. This pigmentation was noticed among the early symptoms, before she came under my care, and led to the diagnosis of Addison's disease by a prominent physician of this city. The tongue is swollen, the mucous membrane of the mouth pale, the soft palate, uvula, and pharynx thickened and relaxed. Her voice is hoarse, guttural, without intonation, and nasal in quality, as if she were suffering from enlarged tonsils. She speaks slowly and with deliberation, but under emotional excitement her manner of talking becomes at times quite natural. When she begins to talk, swallowing movements are often noticed, induced probably by the swollen and dependent uvula. Several times daily, with increasing frequency during the past year, she has attacks of aphonia, beginning and ending suddenly, which are occasioned by mental excitement, fatigue, or prolonged conversation. These attacks are accompanied occasionally by choking sensations, and even alarming dyspnœa. Aphonia and dyspnœa can be produced at any time by moderate pressure upon the trachea, which is apparently diminished

[1] W. A. Hammond, one case (Neurological Contributions, New York, 1881, vol. ii, No. 3, p. [illegible]); F. M. Crisler, one case (Archives of Medicine, New York, 1881, vol. viii, No. [illegible], p. [illegible]); A. M. L. Hemeter, two cases (Medical Record, New York, 1882, vol. [illegible], p. [illegible]; Journal of Nervous and Mental Disease, [illegible] 1882); J. W. Holland, one case (American Practitioner, Louisville, 1883, vol. [illegible], p. [illegible]); I. A. Robinson, one case (Medical Record, New York, 1884, vol. [illegible], p. [illegible]); [illegible] Fagge, one case (Lancet, London, 1882, vol. [illegible], p. [illegible]); Robert T. Edes, two cases (Boston Medical and Surgical Journal, 1885, vol. [illegible], p. 385); E. G. West, one case (Boston Medical and Surgical Journal, 1885, vol. [illegible], p. 501); O. F. Wadsworth, one case (Boston Medical and Surgical Journal, 1886, vol. [illegible], p. 5.

in size, and is certainly more flexible upon pressure than is normal. This abnormal flexibility of the trachea, and the production of dyspnœa by a very moderate pressure, was noticed by Professor Kocher in his cases of cachexia strumipriva, to be considered later. No trace of the thyroid gland can be felt in front of the trachea, but the neck is too much swollen to justify a positive opinion as to the size of the gland.

On the part of the muscular system there is some paresis, but less than would be expected from her gait, which is slow, uncertain, waddling; she readily stumbles, and sometimes falls to the ground. The flexors and extensors of the limbs fail to show marked loss of power; there is no static ataxia. The difficulty in walking seems to be caused rather by lack of harmony in the action of opposing groups of muscles. The nuchal muscles are particularly weak, allowing the head to fall forward upon the chest. There is no apparent muscular atrophy; on the contrary, the muscles appear to be fully developed. The knee-jerk is well preserved; the superficial reflexes weak. Tactile sensation good, and not perceptibly delayed in transmission. No cutaneous anæsthesia, general or local, such as is commonly observed in myxœdema, but rather a noticeable amount of hyperæsthesia. All bodily movements are sluggish. The act of dressing takes up a good part of her morning, and many of her household duties have been given up because she has not time for them. Parallel with the muscular lethargy is the condition of mental functions. With the exception of slight impairment of memory, there is little loss of intellectual capacity, but her mind acts slowly; she is slow in apprehension and expression. The mental process, though retarded, is, however, in the end performed correctly. She is easily annoyed by trifles, and irritable in temper, conditions which are the opposite of her natural disposition. Sight and hearing are both impaired, especially the latter. There is no perversion of taste or smell. Her sleep is often disturbed by unpleasant or frightful dreams. All the vital processes are carried on in a sluggish manner. The pulse is slow, with low arterial tension; heart's action feeble, impulse not felt, but no murmur is audible. The excretion of urea is diminished, averaging but little more than half the normal amount. The urine is pale, of low specific gravity (1.010 to 1.015), lessened in quantity—except during the periods of profuse diuresis before mentioned—and hitherto, at repeated examinations, has never contained albumen or casts. Liver and spleen not perceptibly enlarged. The temperature of the body ranges from 95° to 98°, rarely reaching the latter point; she consequently suffers from exposure to cold, and is worse in winter than in summer. At present her disease seems to be in a comparatively stationary condition.

The second case is strikingly similar to the one just described. C. R——, male, aged fifty-nine, Jew. No family history of myxœdema or of special nervous disease; no personal history of mental shock or anxiety. In 1873 he had a severe attack of intermittent fever; shortly afterward symptoms of myxœdema manifested themselves, and have progressed steadily up to the present time. He now presents the typical symptoms of the disease: swollen face, puffy, wrinkled eyelids, pink cheeks, broadened nose, thick lips, spade-like hands, general solid infiltration of the skin, supraclavicular and suboccipital bolsters of fat; slow, waddling, uncertain gait; peculiar deliberation and nasal intonation of speech. With the exception of a scanty beard the loss of hair is almost complete. The hairs of his head can be numbered without difficulty, as there are none left except a few scattered ones on the vertex and occiput. The baldness is so complete that he is obliged to wear a wig. The scalp is deeply pigmented, of a tawny color, parchment-like, seamed with creases, resembling a piece of tanned leather. Three congenital moles, one on the forehead, one on the right cheek, and another on the tip of the nose, have grown considerably within the past few years, and are now as large as a pea. Six others, smaller in size, have made their appearance on the face, and a few, still smaller, on the scalp. Half of his teeth are gone, the rest badly decayed and loose in their sockets. The thyroid gland cannot be felt in front of the trachea. There is no history of a previous enlargement of the gland. The submaxillary gland is much enlarged on both sides. Saliva dribbles upon the pillow at night, but less now than formerly. As in the previous case, the trachea is unusually small and flexible, and moderate pressure produces marked dyspnœa. Smell and taste not impaired. Dr. Charles S. Bull has kindly examined his eyes and ears, and sends me the following report:

"*Eyes.*—Right eye: Secondary converging squint following paresis of external rectus occurring in childhood. Some œdema of ocular conjunctiva in both eyes. Irides rather sluggish in action; small arcus senilis in corneæ; media clear; no sign of either retinitis, neuritis, or atrophy of the optic nerve. Refraction hypermetrophic in both eyes; vision has always been defective in the right eye, and is normal in the left eye. The veins in the retina of both eyes are somewhat engorged, but no more than is seen in normal eyes.

"*Ears.*—Auditory canals somewhat narrowed from thickening of cutaneous lining; epidermis scaly; drum-membranes sunken, thickened, opaque, and inelastic; uvula long and flabby; mucous membrane of the nasopharynx thickened, hyperæmic, and secreting a rather tenacious mucus; watch not heard in either ear, even when placed against mastoid, squamous, or frontal bones; tuning-fork not heard at all when placed in vibration against frontal or mastoid bones, but patient *says* he hears it faintly when made to vibrate strongly, and held immediately in front of meatus.

"*Diagnosis.*—1. Chronic catarrhal (proliferous) disease of middle ears. 2. Chronic degenerative disease of some part of the acoustic nerve, which may be either primary or secondary to disease of the middle ear.

"CHARLES S. BULL."

He has much difficulty in walking, and requires the help of a cane; but the impairment seems to be chiefly ataxic, as he retains considerable muscular power in all his limbs. Knee-jerk present; superficial reflexes lost; slight anæsthesia of hands and legs. Tactile sensation delayed. Memory perfect about business matters and events of early life, but unimportant recent occurrences he forgets more readily than formerly. He is despondent, irritable, easily annoyed by trifles, and keenly mortified by his personal appearance, which attracts much attention on the street. His handwriting is unchanged, but he writes very slowly. He plays the organ with nearly his former skill, but the clumsiness of his fingers prevents the execution of rapid movements. His wife assures me that she observes no diminution of his mental capacity. In conversation the shrewdness and aptness of his remarks are very noticeable, but talking with him is excessively tedious on account of his provoking slowness. A like torpor affects also his intestinal movements. They require the daily stimulus of a purgative, and even with its assistance a whole hour has to be devoted to the water-closet. Heart's action feeble; no murmur; no increase of arterial tension. His urine, since he has been under my care, has always been free from albumen or casts. Liver, spleen, and lungs present no signs of disease. The bodily temperature is subnormal, and frequently lower upon one side of the body than upon the other; at the last examination it was 96° in the mouth, 95.8° in the right axilla, 96.6° in the left. During the past year he has become more helpless, but in other respects there has been little change.

A few points of special interest in these two cases may be noted:

Heredity.—In the case of Mrs. B—— there is a clear history of both direct and collateral heredity. I have found but one similar case reported, that of Dr. Ord, who says he has seen two daughters who were myx-

œdematous like their mother. Dr. Saville[1] and Dr. Francis Taylor[2] have each reported a case of direct heredity. Several reports mention that one of the parents had died of Bright's disease, and possibly some of the deaths may have been due to myxœdema terminating with renal symptoms.

Influence of sex.—When Sir William Gull first called attention to this disease in 1873, by an article "On a Cretinoid State Supervening in Women in Adult Life,"[3] all of the cases he reported were of the female sex. Dr. Ord's cases, up to October, 1879, six in number, were also females. Of the fifteen cases reported by Dr. Morvan, of Lanniles, in Basse Bretagne, France, in 1881,[4] fourteen were female, one male. As recently as 1882, myxœdema in men was regarded as rare, but since then a considerable number in the male sex have been reported. I have collected reports of 121 cases of myxœdema, and find that of this number 101 were women, 20 men, the proportion of the latter being, therefore, about twenty per cent.

Size of the thyroid and submaxillary glands.—No mention is made of the condition of the thyroid gland in 67 out of the 121 collated cases. Of the remaining 54, in 2 cases slight enlargement is reported, in 7 normal size, in 14 marked diminution in size, and in 31 it is mentioned that the organ could not be felt. Examination of the thyroid in myxœdematous subjects is usually unsatisfactory, owing to the thickness of the tissues of the neck; still there seems to be a very general agreement as to the presence of thyroid atrophy during life, while at autopsies this condition has been always found. In my first patient, and also in her sister, the myxœdematous symptoms were preceded by a temporary enlargement of the gland. Similar cases have been reported by others. A history of exophthalmic goitre has been noted occasionally. In my second case the submaxillary glands were much swollen. I have not seen this symptom reported in other cases; nor, so far as I can learn, has the condition of these glands been examined *post mortem*. Mr. Horsley found hypertrophy of the submaxillary gland in all his cases of thyroidectomy in monkeys.

Condition of mental functions.—Neither of my patients, it will be observed, presented any marked disturbance of the psychic functions. A number of cases have been reported, however, of more serious cerebral lesions, as shown by hallucinations, melancholia, aggressive mania, and imbecility.

For most of our knowledge of the characteristic lesions of this affection, as well as for the name by which it is generally known—myxœdema (μύξα, mucus)—we are indebted to Dr. Wm. M. Ord, of London.[5] The lesions found at his first autopsy[6] were briefly as follows: In the skin marked increase of the fibrillar element of the connective tissue; the nuclear element highly developed and the nuclei enlarged. The interstitial spaces in the connective tissue were large, and filled with "an excess of the mucin-yielding interfibrillar cement." Portions of the skin showed fifty times the normal amount of mucin. Increase of connective tissue was found also in the adventitia of the arteries in the liver, separating the cells from one another and producing atrophy in them, and in the heart inducing attenuation of its muscular elements. The cerebral arteries were extremely degenerated and atheromatous, as were also the great arteries, especially the carotid. No microscopical examination was made of the central nervous system. The kidneys were granular, with thickening of minute arteries and atheroma of renal arteries. The thyroid gland was atrophied; its alveoli compressed, and almost annihilated by the connective-tissue growth around the vessels.

The resemblance of the swollen connective tissue to that of the umbilical cord led Dr. Ord to adopt the view that the essential lesion of myxœdema was a reversion of this tissue to its embryonic state. His views upon this point have since changed, and he now regards the marked development of the nuclear element as indicating that the lesion is rather one of imperfect development.[1] The distinction may not be of much importance, but it is proper that his more mature views should be stated.

The characteristic muscular and mental lethargy of myxœdema was ascribed by Dr. Ord to "the condition of the skin interfering with the natural exposure of the nerve-ends to stimuli." The padding of the peripheral nerves and touch-corpuscles by myxœdematous tissue impedes, he supposes, the transmission of external impressions, and induces inertia of the nerve-centres. But well-marked myxœdema of the skin and sluggishness of movements and mental functions may co-exist in the same patient without noticeable interference with transmission of cutaneous impressions, as in my first case, in which there was no retardation of tactile sensation, but rather a hyperæsthetic condition of the skin. Again, as Dr. Goodhart has pointed out,[2] there is no reason to suppose that in adult life, after the nerve-centres are fully developed, the abolition of a special sense can do appreciable harm to the intellectual faculties. Certainly no such result follows deafness, blindness, or anæsthetic leprosy. Dr. Ord, after discovering lesions of the central nervous system in his third autopsy,[3] conceded that the same changes which occur in the skin certainly exist also in the nerve-centres, and are quite sufficient to account for the nervous symptoms.

In a paper read before the Association Française pour l'Avancement des Sciences, in 1882, Dr. Henri Henrot gives the results of a careful investigation of the nerve-lesions found in a case of myxœdema.[4] In addition to the cutaneous and visceral lesions described by Dr. Ord, he found mucinoid degeneration of the pneumogastric and glossopharyngeal nerves, of the brachial plexus, especially of the ganglia and cord of the great sympathetic, with enlargement of the pituitary body and pineal gland, and concludes that myxœdema is characterized by a return of the subcutaneous, submucous, and interstitial connective tissue to its embryonic state, and by the formation of mucin under the influence of the enlarged pituitary body and pineal gland, which preside over this function.

In a case, with autopsy, reported by Dr. E. M. Cushier,[5] which had presented marked paresis of lower limbs during life, important changes were found in the spinal cord. The walls of the small vessels were thickened and infiltrated with a transparent homogeneous substance. In portions of the lumbar cord, in Clark's columns, and in the lower cervical region, slight hemorrhages were observed. Sections from the lumbar cord showed here and there complete "yellow degeneration" of cells in both anterior and posterior horns, also atrophy of the cells, and absence or diminution of their processes. Similar changes were found, but to a less extent, in the dorsal and cervical regions. "The thyroid gland was smaller than usual, especially the left lobe. The latter had undergone cystic degeneration. The right lobe was of unusually firm texture." On microscopical examination the walls of the alveoli were seen to be thickened, and their contents had entirely disappeared or were replaced by a homogeneous substance.

Lesions of the sympathetic system have been noted in

[3] Lancet, 1882, i., 107.

a number of autopsies. Dr. John Harley,[1] in one case, found the thoracic ganglia deeply implicated in the adherent and degenerated pleuræ. On the left side the ganglia could not be distinguished. Dr. W. M. Hadden, of London, who is a strong advocate of the view that the essential pathology of myxœdema is a lesion of the peripheral sympathetic system, or of its supreme centre in the medulla oblongata,[2] reports that in two cases examined by Dr. Goodhart and himself an alteration resembling sclerosis was found in the cervical sympathetic. "The ganglia were very fibrous, the nerve-tubes degenerated and atrophied, but the cells not apparently affected." In a third case the semi-lunar ganglia were swollen, very firm, and apparently sclerosed. Sclerotic and degenerative changes were observed also in the thyroid gland in all of his cases, but the earliest changes, he maintains, are external to the alveoli, and the organ becomes atrophied secondarily. He admits, however, that thyroid lesion is a constant fact in the morbid anatomy of myxœdema.

Although thyroid changes are invariably found in myxœdema, they are by no means always accompanied by important lesion of the sympathetic. In a recent autopsy by Dr. W. Hale White[3] the thyroid was very small and atrophic. "There was little or no proper thyroid structure left; a few bodies, evidently the remains of vesicles, are to be seen, and in one or two instances just a trace of the epithelial lining still remains. These degenerate vesicles are filled with small epithelial cells, which have been apparently produced by the multiplication of the proper epithelial lining. . . . The whole organ has undergone extreme simple degeneration." Sections were examined from the right middle cervical ganglion of the sympathetic, right superior cervical ganglion, right cervical sympathetic nerve, left superior cervical ganglion, and the semilunar ganglion. In the section from the right middle cervical ganglion "the cells were abundant, very few pigmented; in many a distinct nucleus and nucleolus are visible. Considering how cells may vary in ganglia which we have no reason to think abnormal, these cells appear very healthy; it is true that some are blurred and have no distinct nucleus, but this is not more so than is often the case. The connective tissue has the degenerate, ill-defined, sodden appearance already described; the result of this is that it is pressed on the nerve-cells so as to reduce the size of the capsule, and in several instances the connective tissue is brought in such close contact with the cell that the line of demarcation is not very evident. Here and there this condition obscures the nerve-fibres. There is no small-cell proliferation." In all the other sections the connective-tissue changes were less marked; more nuclei were seen, and the nerve-cells were healthy in appearance. The slight changes found in the sympathetic Dr. White regards as the result, and a not very important result, of the thyroid atrophy.

This brings us to the question as to the function of the thyroid gland; whether it be of such a nature that its abolition is capable of initiating the remarkable series of morbid changes found in myxœdœma? Physiologists have long suspected that this body possesses important glandular functions. Its relatively large size during the period of bodily development—its proportion to the weight of the body during infancy being that of 1 to 240 or 400; in adult life, 1 to 1,800—and the structure of the organ seem to point in this direction. Its vascular supply is so large that "the sum of the sectional area of its arteries is more than half that of the cerebral arteries, while the lymphatics form huge lacunar spaces immediately outside the margin of the alveoli" (Horsley). The acini are lined with epithelium, at first columnar, later cubical, are surrounded with a rich capillary network, and are filled with a homogeneous or finely granular colloid material, identical with that found in the lymphatics of the gland. Berthelot has shown that the blood in the thyroid vein has a very different composition from that in the jugular vein (the former containing 8.81 to 10.92 per cent. less blood-corpuscles and more fluid ingredients than the latter), and Baber [1] has further shown that this colloid material is largely formed by destruction of the red corpuscles, which are found in the vesicles in all stages of disintegration. From this fact he infers that the thyroid gland exerts a general influence upon the composition of the blood. Simon, Schiff, and others have concluded, from experiments on the lower animals, that the gland secretes something which modifies the nutrition of the nervous system, especially the brain. Let us now see what light is thrown upon the subject by the results of thyroidectomy.

Cachexia strumipriva.—In 1883 Professor Kocher, of Berne, Switzerland, reported eighteen cases in which symptoms closely resembling those of myxœdema followed complete removal of the thyroid gland for goitre.[2] His attention was first drawn to the matter by a remark of Dr. Reverdin, of Genf, that two of his operations for goitre had been followed by diminution of mental capacity. Shortly afterward Professor Kocher saw one of his own patients, from whom he had removed the entire gland in 1874, and the remarkable changes which had resulted in her induced him to investigate the condition of all the other goitrous patients upon whom he had operated, 101 in all. It was found that none of the partial operations, that is, operations in which one lobe alone, or one lobe with the isthmus, had been removed, were followed by cretinoid symptoms. Of the 34 total excisions 3 had died from the operation; 2, after healing, had died from unknown causes, and in 1 the cancerous goitre had reappeared. No news was received from 4. Six sent a written account of their condition; 4 of them were said to be in good health, but little value was attached to these reports, as careful examination might have detected incipient symptoms; in the case of the other 2, symptoms were mentioned which corresponded with those observed on personal inspection in the other cases of complete excision. Of the 18 patients with total excision who presented themselves for examination only 2 had remained well; in 1 of them a small accessory thyroid had developed, and in the other the goitre had returned. The remaining 16 all presented serious disturbances of health, the symptoms being more marked in proportion to the time that had elapsed since the operation, and relatively more marked also in those operated on during the period of growth. To the group of symptoms observed in these cases Kocher gave the name cachexia strumipriva (struma-goitre).[3]

The symptoms developed, as a rule, immediately after leaving the hospital, but sometimes only after four or five months. They began in the form of lassitude, weakness, and pains in the limbs, followed by sensations of coldness in the extremities. In winter, especially, the hands and feet became swollen, bluish, and cold, and chilblains were of frequent occurrence. Diminution of mental capacity, with slowness of thought and speech, was also noticed, particularly in the children who were attending school. Ciphering was especially difficult for them, and in recitation they showed so much deliberation and delay in their answers that in some cases the teacher had been obliged to abandon their further education. Some of the pa-

[illegible]

[3] At the time of writing his article, Professor Kocher seems to have been unaware of the existence of such a disease as myxœdema; at least he makes no reference to the cases of this disease reported in England and France. Spontaneous myxœdema in adults in Germany and Switzerland must be very rare, if one can judge from the absence of reported cases in these countries. Moebius, in Schmidt's Jahrbücher (1883, Bd. 198, s. 35), inquires whether the disease occurs only in England and Latin countries, or whether it has been merely overlooked in Germany. Since that date I have been unable to find a single case reported in German journals.

tients, who had been servants, had been compelled to give up their situations on account of their slowness in speech and movements.

In the advanced cases the skin of the whole body was swollen. This change began as temporary fluctuating swellings of the face, hands, and feet, lasting for a few hours, particularly in the morning, most marked in the eyelids, and after some time became permanent. When it was fully developed the face was broadened, the lids swollen and translucent, as in some cases of Bright's disease, the nose and lips thick, and the hands, legs, ankles, and feet enlarged. The body became stouter, especially in the region of the lower thorax and abdomen. The skin was infiltrated, hard, dry, and on the body hung in folds. In two cases there was marked alopecia. In advanced cases the skin and visible mucous membranes were markedly anæmic. The pulse was small, thready, easily compressible; the heart-sounds clear, weak, and the second aortic, still more the second pulmonary sound, accentuated. On examination of the blood all the cases showed marked diminution of the red corpuscles, with relative increase of the white, but no changes in their size or form. Aside from the sluggishness of the mental functions there were few cerebral symptoms. Faintness and headache were occasionally noticed. In one case paroxysms of severe cramp occurred four months after the operation, followed later by epileptic attacks with loss of consciousness. All the cases were examined ophthalmoscopically by Professor Pflüger, but even in the cases of advanced cachexia nothing was observed except a remarkable narrowness of the arteries — no hemorrhages such as are found in progressive pernicious anæmia. The muscles of the limbs, even in those who complained most of weakness and had been obliged to give up work, were so well developed as to remind one of pseudo-muscular hypertrophy. Pulmonary symptoms were not observed, nor albuminuria, except a trace of albumin in one instance. Some of the patients complained of dysphagia, and had difficulty in swallowing dry bread and solid food. Choking sensations in the neck were of more frequent occurrence. In these persons the trachea was more flexible and softer than natural, and apparently atrophied: moderate pressure upon the trachea produced marked dyspnœa. No tracheal atrophy was observed when only a part of the gland had been removed, except slight softening in a few cases on the side of operation. The softening and atrophy were thought by Professor Kocher to be due to ligation of the thyroid arteries in the operation, the trachea deriving its main supply of blood from the inferior thyroid arteries.

Since the publication of Kocher's 18 cases of cachexia strumipriva, 17 more have been reported: Five by J. L. and A. Reverdin,[1] 4 by Baumgärtner,[2] 2 by Julliard, 3 by Professor Bruns, of Tübingen,[3] and 3 by Professor Gussenbauer, of Prague,[4] making, with Kocher's cases, a total of 35; 23 females, and 12 males. One of Professor Brun's cases was of extreme interest, as showing that when the thyroid is completely removed during childhood, bodily and mental development is arrested, just as in sporadic and endemic cretinism. The patient was a young man, aged twenty-eight, from whom, eighteen years before, a goitrous thyroid had been removed by Dr. P. Sick, of Stuttgart. Six months after the operation Dr. Sick had noticed a marked change in his mental condition: "Before the operation he was a bright, cheerful boy; now he is remarkably quiet, reticent, and takes almost no part in the sports of his playfellows; on the other hand, in regard to his ability and willingness to learn in school, and to help his parents in their work, there is no change at all."

Seventeen years later, when Professor Bruns examined him, his condition was as follows: The boyish but plump body is surmounted by the beardless head of a man. The total length of the body is only 127 ctm. (4 feet 1½ inch). While the head is of normal size for his age, his height is that of a boy ten years old. The trunk and extremities are well proportioned to each other. The whole face, particularly the lips and lower eyelids, is much swelled, and idiotic in expression; the skin and visible mucous membranes pallid. The skin of the whole body is dry, scurfy, and thickened by a peculiar brawny infiltration. The hair on the head is very scanty; there is no trace of a beard, and only a few hairs are present on the pubes. The genital organs are well developed. Speech is slow, and evidently impeded by swelling of the tongue, gums, and tonsils. The thyroid gland is absent; larynx and trachea normal; respiration free; heart's action weak. No enlargement of spleen or increase of white blood-corpuscles.

Another characteristic symptom is well developed. While the sensibility of the skin and coarse muscular strength are well preserved, the patient cannot perform the lightest work, and can scarcely walk fifty steps. This muscular incapacity has been complete for several years; when he left school, at fourteen years of age, he was unable to learn a trade or work in the fields, but applied himself industriously to knitting; but a few years later he was obliged to give up that occupation also. There is marked loss of mental capacity. While the boy, before and immediately after the operation, was an excellent scholar, he is now less developed than a child of ten years; his apprehension of ideas is sluggish, and his answers to very simple questions are correct, but very slow. His manner is sober, quiet, but never foolish. Sight and hearing are both defective.

Results of thyroidectomy in the lower animals.—Zesas, in experiments upon dogs and cats, found that after complete removal of the gland the animals remained well for a few weeks, then became drowsy, lost their appetite, staggered in walking, and finally died of convulsions and paralysis. Schiff found in dogs and cats that thyroidectomy was followed by death in from four to twenty-seven days. The symptoms produced were fibrillar contractions of muscles of the extremities and body, attacks of tonic and clonic convulsions, disturbances of sensibility, apathy, somnolence, and death. That the fatal result was not due to lesion of the recurrent nerves, the cervical sympathetic and vagus, was shown by the absence of the characteristic symptoms when the gland was merely exposed, and the thyroid branches of the recurrent and superior laryngeal nerves divided. Similar results were obtained also by J. Wagner. In his experiments no disturbances ensued after partial excision of the gland.

The symptoms following thyroidectomy in the lower animals have recently been restudied by Victor Horsley Brown, Professor of Pathology in the University of London.[1] The operations were performed with strict antiseptic precautions, and with special care to avoid injury to the recurrent laryngeal nerve. In monkeys the symptoms were, briefly, as follows: "At a variable period after the operation, but averaging about five days, the animal is found to have lost its appetite for a day or two, and on closer examination to exhibit constant fibrillar tremor, in the muscles of the face and hands and feet more especially. These tremors disappear at once on voluntary effort. At the same time the animal is noticed to be growing pale and thin, in spite of the appetite returning quickly with great increase; rapidly the tremors increase, affect all the muscles of the body without exception; the animal becomes languid, paretic in its movements, and imbecile. The puffiness of the eyelids and swelling of the abdomen follow, with increasing hebetude. During the last stages the temperature, gradually falling, becomes subnormal, and the tremors gradually disappear as they came. Meanwhile the pallor of the skin often becomes intense; and leucocytosis having become well

marked, oligæmia follows, and the animal dies perfectly comatose in a variable period, but usually about five or seven weeks after the operation."

Sensation was found to be affected only in the advanced paroxysmal stage, and then in the form of slight anæsthesia. The superficial reflexes were diminished, the knee jerk was always well marked, except when prevented by muscular rigidity. The spinal lumbar centres acted normally; no permanent bulbar symptoms, but occasionally transient dysphagia and dyspnœa. Disturbances of the higher cerebral functions were observed in the form of listlessness, irritability of temper, increasing hebetude, and finally partial or complete imbecility. On the part of the circulatory system there were lowered arterial tension, diminution of the red and increase of the white corpuscles, and the presence in the blood of a small amount of mucin. The salivary glands were much enlarged. The submaxillary glands secreted a large amount of mucin, the parotid a less quantity. The secretion of mucin by the latter is worthy of note, because normally the parotid secretion is serous and contains no mucin. The urine never contained albumin, but in some cases there was a transient glycosuria. The skin was very pale, but not dry. The lower eyelids were swelled, the palpebral fissure diminished one-half, and the whole face of the animal presented an appearance similar to that of myxœdema in the human subject.

At the autopsy the subcutaneous connective tissue was "swollen, jelly-like, and shining," and contained from three to four times the normal amount of mucin. Everywhere the connective tissue was notably hypertrophied, but especially in the triangles of the neck and over the hypochondria. There was also an atrophy of fat, as seen in wasting diseases. The muscles exhibited no change except increase of their connective tissue, and the same was true of the circulatory system. Marked indications were found of increase of the mucin-formation function of the alimentary canal. The parotid and submaxillary glands were enlarged to three or four times their normal size, and their cut surface exuded a sticky, glairy fluid. Dr. Halliburton made a chemical analysis of the skin and subcutaneous tissue, tendons, parotid and submaxillary glands and blood, and found a marked increase of mucin in all except the blood, which contained only a trace. The mucous membrane of the intestines was swollen in three cases, and semi-translucent in all. The spleen was hypertrophied, but otherwise normal. In the central nervous system no changes were observed to the naked eye, except anæmia and atrophy, but at the time of the report the sections were not ready for examination. Sections of the cervical, sympathetic, and musculo-spiral nerves were quite normal in appearance.

During the past year, in a new series of thyroidectomies in monkeys, Mr. Horsley found that under the influence of a high temperature the life of the animal could be prolonged to five or six months, with modification of the severity of the neurotic symptoms. Directly after the operation the animals were kept in a room at an average temperature of 90°, and as soon as symptoms occurred, were placed in a hot-air bath with a temperature of 105°. Under this treatment the first symptoms did not appear until ten days or longer, and then were less intense. The monkeys survived the stage of mucinoid degeneration, lost their excess of mucin, and passed into an atrophic stage, in which they died of failure of the lower visceral centres. Such a survival of the mucinoid stage is seen not infrequently also in myxœdema, and accounts for the comparatively slight excess of mucin which has been observed occasionally at autopsies of advanced cases of this disease. The influence of cold in increasing, and of an equable climate in ameliorating, the severity of symptoms in myxœdema was observed in the earlier reports of cases. Dr. Morvan, of Lanniles, in Lower Brittany, France, whose report of fifteen cases has been referred to, expressed his surprise at the severity of the disease in England as compared with the mildness of his own cases. Among his patients, all peasants, one had presented symptoms of myxœdema for ten years, another for seventeen years, a third for twenty years, and yet all three were able to attend to household duties, and engage in active farming work. The explanation, he thinks, lies in the comparatively equable climate of the Finistère, where, owing to the proximity of the Gulf Stream, the temperature rarely falls below the freezing-point. The practical bearing of these interesting observations upon the treatment of myxœdema is obvious.

From the histological structure of the thyroid gland, and the results of his experiments, Mr. Horsley draws the following conclusions:

1. "The thyroid gland appears to consist of two distinct portions: (*a*) glandular, consisting of highly vascular acini, which excrete into their interior a mucoid substance, this substance, or something closely similar, being found in the lymph-vessels of the gland—mucin-excreting function; (*b*) highly vascular lymphoid nodules—hæmatogenous function.

2. "Excision of the gland is followed, according to my experiments, by an increase in the amount of mucin in the tissues which normally possess it, by a retrograde histological change, by an increase in the activity of the glands which normally excrete it, and (what is still more striking) by the assumption of the muciparous function by a gland which normally possesses none or very little mucin—by the parotid gland.

3. "Excision of the gland is followed by profound changes in the blood, viz., a diminution in the number of corpuscles, preceded, as regards the white elements, by a temporary increase in their number, by an alteration in the coagulability and albumens, and by an abnormal presence of mucin.

4. "Excision of the gland is followed by nerve symptoms indicating change in the lowest motor centres, these changes causing tremors with rigidity and paresis; it is also followed by changes in the higher psycho-cortical centres, such producing imbecility, and ultimately death in the comatose state."

In a preliminary note published by P. Albertoni and G. Tizzoni, of Bologna, in June, 1885, two interesting observations are reported in connection with their thyroidectomies in dogs.[1] Examination of the blood several days after the operation showed that the arterial blood contained no more oxygen than the venous blood, sometimes even less. Blood taken from the femoral artery of a healthy dog, kept under the same conditions as the dogs experimented upon, contained 17.8 vols. oxygen to 100 vols. of blood, whereas only 8 to 11 vols. oxygen in 100 vols. blood were found in blood taken from the same vessel in dogs from whom the thyroid had been removed. That neither the deficient oxygenation of the blood nor the other symptoms were due to mechanical interference with the respiratory process was shown by the fact that the same results were obtained in dogs who had been tracheotomized after thyroidectomy.

Albertoni and Tizzoni also call attention to a lesion not mentioned by other experimenters, but defer their final opinion as to its significance until they have examined the central nervous system.[2] The lesion is a degeneration of the peripheral nerves, even of those situated at a distance from the site of operation, *e.g.*, the sciatic nerve, limited to certain portions of the nerve-fibres, and resembling the degeneration found after nerve-stretching. It consists of changes in the medullary sheath, destruction of the axis-cylinder, and increase of the protoplasm of the fibres, with multiplication of their nuclei, especially at points where the degeneration is most advanced.

It has been claimed by several writers that the ca-

[1] Ueber die Folgen der Exstirpation der Schilddrüse. Centralblatt für die Med. Wissenschaften, June 13, 1885.

[2] At the present date (June, 1886) I learn that their complete report has been published.

chetic symptoms which follow thyroidectomy in man and the lower animals are not due to loss of the gland, but rather to injury to the cervical nerves. Thus Baumgärtner[1] ascribes the result in some cases to direct injury of the recurrent nerve, or the thyroid branches of the cervical sympathetic, in the operation, but more frequently to subsequent lesions in one or both of these nerves, induced by processes of inflammation, adhesion, and cicatrization in surrounding parts. The same view has been adopted by Pietrzikowski in his report of Gussenbauer's cases,[2] and also by Dr. Hadden, Dr. Stokes,[3] and Dr. White.[4] This explanation is unsatisfactory for several reasons. In Horsley's thyroidectomies no lesions were found at the autopsies in the cervical, sympathetic, and musculo-spiral nerves, while during life the only symptoms that could be referred to the recurrent nerve were occasional transient attacks of dyspnœa, but no permanent laryngeal symptoms. Moreover, myxœdematous symptoms have never been observed to follow either the numerous experiments that have been made on the cervical sympathetic, or the removal of large cervical tumors, other than those involving the thyroid gland. But even if we admit that during the operation of thyroidectomy, or subsequently, in consequence of adjacent inflammatory and adhesive processes, local injury is inflicted upon the recurrent nerve, or the cervical sympathetic, it is altogether unlikely that such local injury can lead to the widespread changes in the brain, spinal cord, and sympathetic system that have been found in myxœdema, and are, presumably, present also in advanced cases of cachexia strumipriva. The diffuse character of these changes points, with great probability, to some cause outside of the nervous system, which, directly or indirectly, influences it as a whole, and not to a local nerve-lesion spreading by continuity of tissue.

It remains to consider briefly the condition of the thyroid gland in sporadic and endemic cretinism—affections closely allied to myxœdema in the adult. The most striking peculiarity of cretinism, viz., partial or complete arrest of bodily and mental development, we have already seen may follow thyroidectomy when performed in early life. Furthermore, cretins present most of the characteristic symptoms of myxœdema—the broadened face, full cheeks, thick lips, spade-like hands, nasal intonation and slowness of speech, sluggish movements, and many of them also the mucoid infiltration of the skin. Now, in sporadic cretinism the thyroid atrophy is even more marked than in myxœdema, there being no trace of the gland at the autopsy in some cases, as in those reported by Mr. Curling,[5] Dr. Fletcher Beach,[6] and others. In other cases the gland, though present, is atrophied or extremely degenerated, even a small goitre being exceptional. It is a suggestive fact in this connection that deficiency of the thyroid body, as the result of disease, has never been observed except in connection with cretinism or cretinoid symptoms.

But it will be objected that in *endemic* cretinism, the more common form, goitrous enlargement of the gland is the rule. According to the reports of the Sardinian Commission in 1848, and of the French Commission in 1873,[7] two-thirds of endemic cretins are goitrous. Of the remaining third it is merely stated that they had no goitre, but the exact condition of the gland, whether absent or atrophied, is not mentioned. Dr. Hadden, in his paper on "Myxœdema" at the recent Medical Congress in Copenhagen,[8] asks whether "the goitre of the cretin has the same structure as the goitre of the non-cretin? If so, it is clear that the essential cause of cretinism is not the goitre." No investigation has ever been made, so far as I am aware, as to the comparative amount of thyroid degeneration in the two classes; but there is at least presumptive evidence that the goitre of the cretin is more degenerate than the goitre of the non-cretin. Hilton Fagge[1] has pointed out that, when a family moves into a region where goitre is endemic, goitre first appears, and cretinism does not present itself until the second or third generation. It is a fair inference from this fact that the thyroid gland has become progressively more degenerate in the descendants, and this inference is confirmed by the probable existence of a greater or less degree of atrophy in one-third of the cases.

It is difficult, then, to resist the conclusion that the thyroid gland has important metabolic functions, and that in many cases its loss, either by operative removal or by the slower processes of disease, must seriously impair the general nutrition of the body, especially that of the nervous system. In what order of development the lesions of myxœdema follow the loss of thyroid function we can only conjecture. Possibly, the mucoid infiltration and enormous connective-tissue dystrophy may be determined directly by withdrawal of the part taken in the metabolic processes by the thyroid gland, and the nerve-lesions, in part at least, may be the result of compression by hypertrophied connective tissue. It seems more probable, however, from the symptoms following thyroidectomy, that the loss of thyroid function modifies the nutrition of the nervous system directly. Upon this view the connective tissue changes may be regarded as a neurotic dystrophy, and the more important symptoms as due to lesions arising from defective nutrition in the brain, medulla, spinal cord, and sympathetic system. But these are points upon which our present knowledge does not warrant positive conclusions. The object of this paper has been accomplished in directing attention to the highly probable, if not conclusive, evidence that in myxœdema the determining factor in the group of lesions is the one which is the most constant and conspicuous, viz., degeneration and atrophy of the glandular elements of the thyroid body.

SELECTED CASES OF LAPAROTOMY.[2]

By DUDLEY P. ALLEN, M.D.,

THE cases of abdominal section presented in this paper have been selected, not to show brilliant results, but rather difficulties encountered in operation. Some of these difficulties have been successfully overcome. Others, though insuperable, have not prevented recovery.

We present five cases: The first was an exploratory incision in a case in which extra-uterine pregnancy seemed the most probable diagnosis; the second, an interstitial fibroid; the third, an unusually adherent ovarian tumor; the fourth, a double ovarian tumor; the fifth, a dermoid cyst. Four of the cases recovered, one died. The cases will be detailed very briefly, and only the prominent features dwelt upon.

The first case was the patient of Dr. H. J. Lee, of Cleveland, and was seen in consultation with him and Dr. W. J. Scott. The patient, Mrs. D——, aged thirty-three, had been married eight years, she miscarried once seven years ago, and had one child, two years of age, living. Her previous health had been good, and she had suffered from no uterine disease.

Early in April, 1885, she menstruated; not menstruating in May, and experiencing considerable nausea, together with the sensations of her previous pregnancy, she supposed herself pregnant. About June 1st, while in church, she had quite a severe hemorrhage. She was carried home, but bled little after her arrival, but says a little fleshy material came away, though she retained nothing looking like a fœtus.

[1] [illegible]

[2] [illegible]

She was admitted to Charity Hospital, July 14th. Since the time of her supposed miscarriage the patient had suffered from continued abdominal pain and occasional bloody discharge from the uterus, and after entering the hospital had a fever varying from 99° to 101°. She had had two physicians, both of whom considered the case to be a miscarriage. She was anæmic and somewhat emaciated. Examination per vaginam showed a patulous os, with the uterus slightly deflected to the left, having a depth of three inches. In the right iliac region, equally distant between the cæcum and the uterus, was a spherical, semi-fluctuating mass to be felt, both externally and per vaginam. This was somewhat tender on pressure.

Previous to my seeing the case the interior of the uterus had been explored by Dr. Lee, and found empty. The diagnosis was between a malignant or inflammatory disease of the cæcum, a cyst, a local peritonitis, and extra-uterine pregnancy. The latter was considered most probable. Nearly four months having elapsed since menstruation, the most favorable time for the destruction of the fœtus by electricity had passed. The propriety of the application of electricity was, however, carefully considered, but the condition of the patient was such as to make the delay necessary for its application and the determination of its success or failure seem unwarrantable. An exploratory incision was determined upon, and was made August 6th. An aspirating needle was plunged through the wall of the vagina into the tumor, to see if any information could be gained by this means; only a drachm of clear fluid was obtained. An incision was then made parallel to and one inch above Poupart's ligament, extending from the anterior-superior spinous process of the ileum on the right side to the outer border of the rectus muscle. The peritoneal cavity being opened, an adherent mass was found filling the length of the incision. Dense, heavy bands of adhesion extended from this toward the right side of the uterus, and included the fimbriated extremity of the tube, but neither uterus, ovary, nor the tube proper were involved in the mass.

These adhesions were divided between ligatures. A persistent effort was made to reach the centre of the mass by separating the adhesions which surrounded it, tearing them away successively from the superior, inferior, and internal surface, but all these efforts were unsuccessful. Nothing save an extensive destruction of adhesions was accomplished. Further operative interference being denied, unadvisably the abdomen was closed. The diagnosis remained undetermined between abdominal pregnancy, malignant or inflammatory disease of the cæcum with adhesions, and a local peritonitis. Within a few days after operation the patient's fever ceased, and she made an uninterrupted recovery. At the present time the patient is in perfect health, and only a small mass can be felt where the oval tumor formerly existed.

The question of diagnosis was at the time, and is now, uncertain. The recovery of the patient excludes, however, malignant disease; a cyst was excluded by aspiration. A salpingitis or oöphoritis, with pelvic cellulitis arising therefrom, was excluded by the fact that neither uterus nor appendages were included in the adherent mass. That it was simply inflammatory seems improbable, from the fact that the immediate effect of the operation was to reduce the temperature, which soon became normal; that the pain, which had been constant, disappeared, and that the mass, which had been steadily increasing, at once began to decrease in size. If the case were one of extra uterine pregnancy the effect of the operation was to break down adhesions, destroy the vascular supply, and thus prevent the further development of the fœtus. The insertion of the trocar would have the same tendency.

The question of diagnosis and operation, in cases of extra-uterine pregnancy, is an unusually difficult one, both because cases do not present themselves for examination until perhaps the membranes have ruptured and hemorrhage occurred, and also because the determination of the positive existence of extra-uterine pregnancy is sometimes well-nigh impossible. Should even a probable diagnosis be made, it would seem that the question of some operative interference should be seriously considered. This is demonstrated by a specimen which we present to you of ruptured tubal pregnancy at the fourth month, resulting in death. Could this have been diagnosticated, operation would have been easy, and a cure reasonably certain. The specimen shows the fœtus surrounded by amniotic fluid and membranes, with the portion of the tube occupied by the placenta ruptured. Death followed the rupture in about ten minutes. There were absolutely no adhesions, and at the post-mortem only the tube had to be divided to remove the fœtus.

Case II.—Mrs. P——, aged thirty-seven, married, general health good, had been troubled for over a year with difficulty in micturition.

Should she go without micturition for more than one to two hours it became impossible, and catheterization had to be resorted to.

The case was under the charge of Dr. F. J. Weed, and was seen in consultation with him and Dr. H. K. Cushing. The catamenia recurred every three weeks or a little more, and were of late excessive. Examination showed the uterus to have in its wall a dense tumor, firmly wedged into the pelvis so that it could not be moved. The sound entered the uterus four and a half inches. The fundus could be felt above the pubis. In order to relieve the difficulty in micturition, an effort was made to lift the uterus out of the pelvis by means of an inflated colpeurynter. This was continued three days, but produced pain, tenderness, and a temperature of 101°, so it seemed best to remove it. It was then thought possible that the fibroid which bulged into the uterus might be removed through the vagina. Being firmly surrounded by the pelvis, it seemed that by dilating the cervix, and using ergot, and applying pressure from above, the tumor might be crowded downward, since it could go in no other direction.

Treatment by fl. ext. ergot was continued during four weeks. It was administered hypodermatically, by mouth and by rectum, and caused slight decrease in the size of the tumor. Administration by rectum of one drachm night and morning was most efficient and caused least disturbance.

Since the progress was not satisfactory, July 2d, four weeks after entrance to hospital, the patient was etherized, and the cervix was incised bilaterally up to the vagino-cervical junction, and the cervix was dilated as widely as possible with a large Sims dilator. The cavity of the uterus was explored with the finger, and the fibroid did not bulge into the cavity sufficiently to warrant an attempt at immediate enucleation. With this incision, and dilatation of the cervix, it was hoped that by the use of ergot and pressure externally upon the fundus the fibroid might be forced downward. The patient's temperature did not go above 98.8°, and the tumor bulged downward a little, but not sufficiently to warrant an operation for its removal per vaginam. About three weeks after operation the patient went home. Passage of urine had become normal. The tumor was considerably diminished in size, and the loss of blood was less. In November the patient was seen again, in consultation with Drs. Weed and Cushing. Of late there had been considerable increase in size of tumor, and the menstrual periods had recurred about once in three weeks, and the loss of blood was excessive. It was decided that the patient's only chance for health, and almost for life, was to remove both tubes and ovaries. Accordingly, on November 3d, the abdomen was opened. To do this was extremely difficult, for the bladder was found spread out over the front of the tumor, reaching half way from the pubis to the umbilicus, the peritoneum being reflected

horizontally from the abdominal wall to the top of the tumor above the fundus of the bladder. Only one ovary could be felt, and both ovaries and tubes were so impacted in the pelvis that their removal was utterly impossible. The only thing remaining was to close the abdominal incision, which was a complicated procedure. The patient progressed satisfactorily until eleven days after operation, when the left leg was found to be largely swollen. The swelling continued, and the leg was somewhat painful, presenting every appearance of a thrombosis of the iliac vessels. The swelling of the leg gradually decreased, and the patient made a good recovery, leaving the hospital December 18th. At present the patient is in better health and flesh than for a long time. Her menstrual periods have recurred at from four to seven weeks, being much less frequent and severe than formerly. Micturition is normal. The patient says that if she did not know about the tumor, she would be unconscious of its presence. The fibroid is much smaller than at the time of the operation, as evinced by its greatly increased mobility. The history of the case would seem to indicate that the abdominal incision resulted in a thrombosis of the uterine plexus of vessels, which extended to the iliac vessels, thus causing the swelling of the left leg.

The history of the case gives rise to two questions. Has the decrease in size of the tumor been caused by the thrombosis of the uterine plexus of vessels, or has the simple incision produced a change in nutrition, of a sort not fully understood, but well-recognized in its influence upon various diseased abdominal conditions?

Case III.—Mrs. P——, aged thirty-five, married, entered the hospital in March, 1885, the patient of Dr. G. C. Ashmun. She had been visited by several gentlemen, and the case had at first been considered one of pregnancy. She was seen the last of March in consultation with Drs. Ashmun and W. J. Scott. The patient was greatly emaciated, being so thin that she was obliged to lie lengthwise upon a pillow. She sat up a short time each day, but could not walk. She ate almost nothing. Her pain was so intense that she had one grain of morphine hypodermatically every night. The abdomen was very prominent, and so tense as to look like parchment. The pulse before operation ranged at about one hundred. All agreed upon a diagnosis of ovarian tumor, and that though an operation offered the only chance for life, the case was wellnigh hopeless from the condition of the patient, and the probability of extensive adhesions. There was great fear lest the patient should die on the table.

The operation was performed April 2, 1885. The tumor was adherent to the abdominal wall over its entire anterior surface, but these adhesions were not difficult to separate. The whole superior surface was closely adherent to the omentum, and this had to be divided between successive ligatures. The posterior surface was adherent to the small intestine, and at least one yard of gut was removed from the cyst by slowly tearing between thumb and fingers the adhesions. There were also adhesions to the pelvis on both sides, and the pedicle, which was not over one inch long, was adherent to the pelvis on the left side, and to the sigmoid flexure. To tie it was the most difficult part of the operation, and when tied it was not less than one and a half inch in diameter. The bleeding was excessive, being most abundant from the intestines and mesentery. A large number of vessels were tied with catgut, but since the hemorrhage still continued from the intestines and mesentery, at the suggestion of Dr. Mellikin towels were wrung out in hot water and repeatedly inserted deeply into the abdomen, beneath the bleeding intestines. This controlled the hemorrhage. The time occupied in the operation was two hours and ten minutes, and the difficulties overcome were extreme. The patient was in a state of collapse when put to bed, and it was thought in the night she was dying. She was kept up with artificial heat, subcutaneous injections of brandy and enemeta of brandy, beef-tea, and laudunum. She improved slowly, sitting up in bed three weeks from the day of the operation, and made a good recovery. The case has been related as one which recovered under the most adverse circumstances, and also to show a method of stopping a general oozing of blood in the abdominal cavity, by the application of towels wrung out in hot water. Though this is a common method in other locations its advantages have not perhaps been sufficiently recognized in hemorrhages deep in the abdomen. Having employed it on various other occasions we can commend it as a valuable and safe procedure.

Case IV.—Miss G——, aged twenty-six, slender; noticed a growth in her abdomen in July, 1885. This increased gradually. The case was under the charge of Dr. H. J. Lee, and was seen, in consultation with him and Dr. W. J. Scott, October 27th. The case seemed to be one of simple ovarian cyst, probably without adhesions. It was operated on October 29th. One cyst, which weighed eight pounds, was easily removed. After its removal, a second cyst, about three inches in diameter, was found to involve the other ovary. This lay on the floor of the pelvis, being thick and dense. To remove this cyst it was necessary to ligate, and divide into two portions the broad ligament. The cyst had its point of attachment to the right and posterior surface of the uterus, almost down to the utero-vaginal junction. The only thing to mark the operation was the weakness of the patient's pulse. This had averaged ninety before the operation, and became very feeble. The pulse, which was 112 the evening of the operation, gradually increased until, on the fourth day, it was 142. The day before a slight discharge had appeared from the vagina, resembling that of menstruation. The temperature had reached 103.2°. The chief difficulty, however, seemed to be the weakness and feebleness of the pulse. The tympanites was only moderate. It became evident that without some relief the patient must die.

Since the vaginal discharge made the presence of some septic process seem possible, the only indication was to relieve this. Accordingly, a vaginal douche was given, and the lowest stitch in the abdominal wound was removed, and a Kerth drainage-tube carried down to the bottom of Douglas' pouch. Not more than two teaspoonfuls of bloody serum were obtained. One quart of a solution of thymol, 1 to 1,000, at a temperature of 99°, was then injected into, and again removed from, the abdominal cavity. The patient endured all this without ether, and said it caused only a little smarting. There was no exhaustion, and patient was, if anything, more comfortable after than before the operation. The urine, which had been scanty, measured, at next catheterization, nearly one pint. The patient gradually failed, the pulse growing more rapid and feeble, and she died about four and a half days from the time of the operation. The autopsy was performed about twelve hours later. There was considerable tympanites. No fluid was found in the abdominal cavity, nor the slightest sign of any inflammation. There were only nominal adhesions to the points where the tissues had been divided. The uterus, which was removed entire, and which is presented to you, shows the ligatures intact and the uterus in a normal condition. The kidneys were examined, but nothing abnormal could be discovered in the appearance of the abdominal viscera or cavity. No signs of sepsis could be found. We were not permitted to open the thorax. It would have been interesting to have examined the heart, to see if a clot had caused the weakness of its action. Its failure had been out of proportion to the gravity of other symptoms, and has produced the conviction that the weakness of its action was a leading factor in the outcome of the case. Examination of the point of attachment of the right ovary will show the difficulty of its removal. The case is interesting as demonstrating that what would seem a simple case before oper-

ation, may possess unseen elements of difficulty, and result fatally.

Case V.—Mrs. C——, aged twenty-seven, married, in excellent general condition, was operated upon October 22, 1885. The case was seen in consultation with Drs. H. K. Cushing and W. J. Scott. An ovoid mass was found to the right of the uterus, semi-fluctuating, and was thought to be separate from the uterus. Its nature was not determined. It was removed without any unusual incidents. On being opened it was found to be a dermoid cyst, containing about one and a half pints, made up of sebaceous material and hair. Attached to the wall was a piece of bone, and upon this were growing two well-formed teeth. You may be interested to see it. The convalescence proceeded remarkably well, with the exception of one complication. A week after operation the patient developed a universal and very severe bronchitis. Careful treatment was followed by marked improvement after twelve hours, and after twenty-four hours the danger was past, and the patient made an uninterrupted recovery.

The foregoing cases have all been performed with the strictest precautions with regard to cleanliness and antisepsis. Carbolic acid and bichloride of mercury have been used, great care being exercised that none should enter the abdominal cavity.

They have been reported to show, first, the difficulty of diagnosis in extra-uterine pregnancy; second, to record the presence of an unusually developed bladder, greatly endangering operation; third, to record the benefits following an exploratory incision in a case of uterine fibroid with excessive hemorrhage; fourth, to record the successful removal of an ovarian tumor with almost universal adhesions; fifth, to emphasize a desirable method of controlling excessive bleeding deep in the abdominal cavity, by means of cloths wrung out in hot water; sixth, to show that the weakness of the heart may prove a serious complication after ovariotomy.

A NEW VAGINAL IRRIGATOR.

By JOHN W. GORDON, M.D.,

PLYMOUTH, ME.

Recumbent position of the patient, long-continued application of copious injection fluids of high temperature, such, in brief, are the more essential factors in successful vaginal irrigation, as evinced by the clinical experience of the modern gynecologist; and it is to be borne in mind that the external female genitals will not bear contact with that high degree of heat which is well tolerated by the vaginal canal and cervix uteri, and which is demanded in the management of various pathological states of the pelvic viscera.

The many vexatious inconveniences which attend the measures usually employed in private practice for administering vaginal irrigation often disgust or discourage the patient, and thus in many instances absolutely bar a continuation of the process, more especially when injection fluids of the highest requisite temperature are ordered; while the inefficiency of such measures, even when faithfully carried out as far as practicable, so detracts from the just and possible results of this invaluable method of medication as to frequently disappoint the expectations of the physician and patient alike.

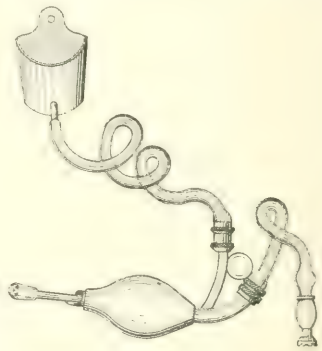
An instrument has been recently constructed for the purpose of wholly relieving patients of such inconveniences and discomfort as well as for greatly enhancing the efficiency of this method of treatment, and the unique device is being used with most gratifying results.

The instrument consists of an injection-tube, which may be attached to, and operated by, all kinds of syringes—the ordinary rubber-bulb, alpha, fountain, or hydrant. This injection-tube is surrounded—a portion of its length—by a larger tube, which supplies means of ample drainage. Surrounding the intra-vaginal portion of the drainage-tube, and attached thereto, is a hollow, soft rubber bulb or tampon, conical in form, elastic and compressible, which, when the instrument is inserted within the vagina, gently and perfectly occludes the orifice of that canal, thus preventing the surplus injection fluid from escaping therefrom otherwise than through the drainage-tube, which communicates with a receptacle which is placed on the floor at the side of the bed or couch.

Thus, while this elastic and compressible tampon affords absolute immunity from leakage, it also, by means of the inclosed air-chamber, protects the sensitive vulva and perineum from undue contact with heat, thereby enabling the patient to make use of injection fluids at the highest requisite degree of temperature with entire impunity during the most lengthened period of irrigation.

Patients—without the aid or presence of an attendant—conveniently and willingly operate the instrument in an efficient manner while occupying every variety of the recumbent position; indeed, all desirable postures are equally available, and no accessories whatever are required.

By virtue of the peculiar mechanism of this device and the simplicity of its operation the user easily controls the mechanical action of the injection fluids employed. Thus by simply compressing the drainage-tube between the finger and the exterior of the ring by which the instrument is held in place—thereby obstructing the outflow—the vaginal canal may, whenever advisable, be distended to the fullest extent by the gentle means of equable hydrostatic pressure, by which manœuvre the rugæ are thoroughly separated and the irrigating liquid finds direct access to the entire mucous surface of that organ, and may be thus retained indefinitely; while by means of the dependent position of the drainage-tube the injection fluid—obeying the fundamental law of hydraulics—wholly escapes from the vagina ere the instrument is withdrawn from its position at the termination of each period of irrigation; and hence, whatever the posture of the patient, and whatever the properties of the liquid used, perfect cleanliness of person and the avoidance of wetting or soiling clothing or bedding is insured from first to last.



The smallness of the apex of the tampon—five-eighths of an inch in diameter—renders the device no less available to the maid than matron.

The small size of the entire instrument renders it easily kept from the observation of children, as well as from the prying eyes of children of larger growth; while its portability renders it eminently serviceable to those who journey in pursuit of health, "the conventional saturnalia of bucket-blankets, pans, stools, and so forth," being left behind, laid away to be numbered with the lost arts.

Equipped with this irrigator I order systematic and thorough hot vaginal irrigation in the recumbent posture, with full assurance that in every instance my instructions will be promptly and faithfully followed by the patient,

who dispenses with the services of attendants, together with the whole paraphernalia of aids, and in the seclusion of her room secures all the benefits to be derived from the most advanced surgical art as conveniently and in as cleanly a manner as she can make or unmake her accustomed toilet, and feminine æsthetics is no longer outraged.

Progress of Medical Science.

A Method of Removing Foreign Bodies from the Ears.—Mr. Jonathan Hutchinson writes in the *British Medical Journal* concerning a simple method used by him in the extraction of foreign bodies lodged in the external auditory meatus. It consists in the use of a silver wire-loop, instead of either forceps or scoop. He has never, since he was a student, used either of the latter instruments; and, for the purpose of extracting hard bodies from the ear, holds that they are most dangerous. With a flexible silver wire-loop, or if need be, with two placed at right angles, he says he has repeatedly succeeded when all other means had failed. Thus, not only is the loop quite devoid of danger, but it is both more easy of use and far more efficient than any other method. It is impossible that it can injure the membrana tympani, or the walls of the canal. The method of procedure is, after having put the patient under an anæsthetic, to introduce the loop gently into the ear, and turn it about until it is believed to have got behind the foreign body. This it will often do at once; but sometimes a little patience is necessary. In one instance the writer took out a piece of heavy lead in this way with very little trouble, using two loops at right angles with each other. The simplicity, safety, and efficiency of the method make it desirable, he thinks, that it should be better known.

Albuminuria during an Attack of Prurigo.—Dr. Umberto Dieci reports the following case in a reprint from the *Gazzetta degli Ospitali*. A shoemaker, thirty-four years of age, had suffered for nearly his whole life from prurigo of the entire body. At the time of coming under treatment, after an aggravation of the skin affection, he had œdema, beginning in the face and thence spreading over the rest of the body. The urine was found to be albuminous, but this together with the œdema, quickly disappeared under appropriate treatment. Six months later the œdema again appeared, and the patient was received into hospital. At that time the prurigo was marked and the œdema extensive; there was great hypertrophy of the heart, a systolic murmur was audible at the apex, albumin and casts were found in the urine. In the course of a month the cutaneous affection became better, the œdema disappeared, and the urine became normal. The treatment consisted in warm baths and the hypodermatic injection of pilocarpine. No albumin was found in the perspiratory secretion. The writer believed that the kidney affection was secondary to the skin disease.

Collapse after Antipyrin.—Dr. Blore relates the case of a woman who suffered from a fever following abortion. Quinine was first given, and then antipyrin. Of the latter drug a dose of thirty grains was given, and three hours later fifteen grains more. After the second dose she went into a collapse, and died at the end of about thirty hours, in spite of every means employed to excite a reaction. The author believed the fatal collapse was not a result of the disease, but was caused by the rapid fall of temperature induced by the antipyrin.—*Wiener Medizinische Wochenschrift*, No. 15, 1886.

Infantile Atrophy of the Extremities.—This peculiar affection has been observed and described by Charcot and Marie, Ollenburg, Eichhorst, and Joffroy, some thirty cases in all having been reported. The affection begins in the muscles of the feet and legs, affects those of the thigh but never of the trunk. Then there is a pause of several years in the progress of the disease, after which the muscles of the hands and forearms begin to atrophy, but those of the arms, shoulders, and face are never affected. M. Joffroy reported two cases of this nature at a meeting of the Hospitals Medical Society of Paris (*L'Union Médicale*, May 1, 1886). One of these, a young girl, had been in good health up to the age of five, when she had an attack of scarlatina. Seven or eight months after it was noticed that she did not walk very well, the toes turning inward and the child meeting with frequent falls. A diagnosis of talipes equino-varus was made, and tenotomy was performed and an orthopædic apparatus applied. There was no improvement. A little later, examination showed the foot and toes to be motionless, cold, and cyanotic, and chilblains caused much trouble. The patient could stand with difficulty, and stumbled in attempting to walk. All these troubles were developed in the space of one year, and then there was an arrest in the course of the disease for a period of five years. When the girl was eleven years of age, without any apparent cause, the muscles of the upper extremities commenced to atrophy. The hands tired so rapidly during piano exercise that the teacher was the first to notice the trouble. The thenar eminences grew rapidly thin, and soon the atrophic *griffe* was formed by permanent extension of the first phalanx and atrophy of the second and third. At the time of the report the faradic and galvanic contractility had disappeared in the lower extremities, and while some of the muscles of the upper extremities responded faintly to the electrical stimulus, the reaction of degeneration was present. M. Joffroy thinks that the clinical picture of this form of atrophy is sufficiently defined to warrant a distinctive name for the disease. Heredity seems to play an important part in the etiology of the affection, as of the 30 cases recorded up to the present time, 25 were observed by different physicians in members of one family.

A Peculiar Symptom called by Atropine.—Dr. Rampoldi writes in the *Annali Universali di Medicina e Chirurgia*, that, having a slight conjunctivitis, he instilled into the eye a drop of what he supposed was a solution of zinc sulphate, but what was really a twenty per cent. solution of atropine. He was surprised to feel no smarting. About fifteen minutes later he had the sensation of a dancing white light, apparently just on the borders of the eyelids, which disappeared after a time, and returned whenever the field of vision was disturbed. The same phenomenon was observed in others upon trial with atropine and duboisine.

An Italian Predecessor of Pasteur.—The claim is put forward in a secular journal, *Il Popolo Pisano*, that Dr. Eusebio Valli first made use of inoculations for the prevention of rabies in 1799. In a book upon the "Plague of Constantinople," he gave an account of inoculations of animals with the saliva of a mad dog, modified by admixture with gastric juice. Finding no ill effects resulting from these experiments, he then inoculated the child and the maid of a lady of Pisa, who had been bitten by a rabid dog, and they escaped without any bad symptoms. A similar claim, it will be remembered, was made on behalf of Pacini, concerning the discovery of the comma bacillus. It seems to be the fate of Italians to make discoveries which are at once forgotten, until they are rediscovered by some French or German worker. It would be a patriotic act for some Italian of leisure to ransack the medical literature of his country for the past century or two, and to collect and publish anything which might be suspected to have in it the germ of a great discovery, and thus secure a sort of copyright on it so as to circumvent any adventurous foreigner who might think he had found out something new.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 10, 1886.

SUBLIMATE SOLUTIONS AND THEIR DANGERS IN OBSTETRICS AND SURGERY.

THE use of corrosive sublimate in the dressing of wounds is as old as Paracelsus, but its systematic adoption dates back only five years. Davaine in 1873, and Billroth in 1874, showed the germicidal power of the sublimate, and, acting on Davaine's suggestions, Tarnier in 1881 recommended it for disinfecting the hands; while in 1882 he substituted injections of sublimate solutions for those of carbolic acid in the wards of la Maternité. In this same year Schede and Kummel, basing their plan upon the experiments of Koch, applied corrosive sublimate to general surgery, and since the announcement of their results its use has rapidly increased in this country and in Europe.

Up to the beginning of this year the use of corrosive sublimate dressings and of corrosive sublimate as a wash and injection has been reported upon favorably by twenty-three surgeons and physicians, according to Dr. Lucien Butte, who has written an elaborate article upon this subject in *Nouvelles Archives d'Obstétrique et de Gynécologie.* Among obstetricians and gynecologists Schroeder, Hegar, Stegman, of Dresden; Keller, of Bern; Leopold, of Dresden; Toporski, of Breslau, have made favorable reports upon its use. Articles upon this subject are now appearing in a Vienna journal, from Professor Braun. We note a total of 2,078 cases reported, with only 7 intoxications.

Some have stated that since the use of sublimate they have had no more parametritis.

Dr. Butte is not content with this record, however, and he has industriously collected all the instances of mercurial intoxication, fatal or otherwise, which have been reported.

The first discordant note in the concert of eulogium was struck by Dr. Stadfeldt, of Copenhagen, in 1884. In using washes of sublimate 1 to 1,500, he observed, among seven patients, death in one case and diarrhœa with gingivitis in two cases. In the case of death there were bloody stools, and on autopsy characteristic renal lesions were found.

Hofmeier, assistant in Schroeder's clinic at Berlin, has observed three cases of mercurial intoxication, two being fatal. In these cases vaginal irrigations of a 1 to 1,000 solution were used. Vohlz (*Schmidt's Jahrb.*, 1884, No. 3) reports a case of fatal poisoning following an intra-uterine injection of a 1 to 750 solution. Dr. W. Thorn, assistant at the clinic at Halle, has reported two fatal cases, and one non-fatal case of intoxication. In one of the fatal cases vaginal irrigations, in the other intra-uterine injections, of 1 to 1,000 were employed. Keller, of Bern, reports, during the year 1884–85, four non-fatal and one fatal case.

At the Gynecological Society of Berlin, Lower and Veit each reported cases of lacerated perineum which were sewed up, and injections of a 1 to 1,000 solution used. The patients died with sanguinolent diarrhœa. Drs. Müller, of Bern; Netzel, of Stockholm; Partridge and Peabody, of New York, have reported one or more cases of fatal mercurial intoxication.

E. Fraenkel, of Hamburg, among fourteen autopsies made upon Schede's patients (all of whom had been treated with antiseptic dressings), found evidences of toxic irritation of the large intestine in all cases, and in two instances he attributed death to the mercury.

Finally, three fatal cases are reported by Krukenberg and Ribbert, of Bonn; one by Winter, two by Braun, and two by Mickulicz. Besides this long list of fatal cases, Butte has collected reports, from six observers, of several non-fatal cases. Naturally, only a small part of these cases, however, would be likely to be published.

It thus appears that over thirty cases of death have already been recorded from the use of sublimate solutions, either in the form of vaginal or uterine irrigations or in the washing and dressing of wounds.

The clinical symptoms in this form of poisoning are already so well defined that the diagnosis is not difficult. The drug seems to act, as a rule, on the lower part of the bowel, salivation and stomatitis being rarely observed. The patients first have diarrhœa, then soon complain of rectal tenesmus; finally the diarrhœa becomes bloody, fetid, and profuse, with acute rectal and abdominal pains.

In non-fatal cases the mouth is much oftener affected than in those that are fatal. Nausea and vomiting are generally present.

The amount of urine is lessened, albumen and casts, and sometimes mercury, appear in it. The nervous system shows signs of great depression, but intelligence is not impaired.

Post-mortem, the two most marked and characteristic changes are a gangrenous enteritis, and deposits of amorphous masses of oxalate of lime in the kidneys. This latter change is not always present, but when it does occur it is said to be absolutely pathognomonic of mercurial poisoning.

Occasional fatal mercurial poisoning from sublimate washes and dressings is thus established beyond doubt. But it will be noted that in the majority of cases the solutions used were strong, *e.g.*, 1 to 1,000, or even 1 to 750. Such solutions are to be very carefully applied to open surfaces of the human body. With proper precautions sublimate solutions need not be regarded as dangerous. They may have killed tens, but they have saved thousands.

ENTRANCE EXAMINATIONS FOR MEDICAL COLLEGES.

ONE at least of our leading medical colleges has finally arrived at that point of worldly prosperity when it is able to seriously consider the subject of the elevation of the

standard of medical education. It is universally conceded that in the line of such elevation lie entrance examinations and a graded course of instruction. The former is, we think, of more importance, and is the initial step in the whole matter. Given, then, the probability of consummation of this end, so long hoped for in New York, the question arises, what should be the ground covered by such examinations. In other words, what is the ideal preparation for medical study.

We have to guide us in the decision the experience of other institutions, especially those which form an integral part of a university system. At Yale, for instance, the requirements are algebra to quadratics, Euclid two books, the metric system, and elementary physics. The examinations are all conducted in writing, and the papers handed in are regarded as a test of the candidates' attainments in grammar, spelling, and construction. At Harvard the requirements are that "a student shall pass a satisfactory examination in English, Latin, Physics, and some one of the electives, Botany, French, German, elementary algebra, or plane geometry." In both these institutions, as well as in others, where entrance examinations are required, a candidate is excused from competing if he can present a degree in Letters or Science from some recognized literary institution, or a certificate of entrance to some one of the larger colleges.

This whole subject has been quite thoroughly discussed in a recent address before the Massachusetts Medical Society by Dr. Hodges, of Boston. His criticism of the present methods is seen in the following words: Commenting upon the Harvard requirements, he says that if instead of this a knowledge was alone demanded of the comprehension of those principles "which govern the action of living things, and which are the substrata of human anatomy and pathology, a great gain would be made." He asserts that no field offers a wider scope for the application of various accomplishments than does medicine, and that what we need is men of mental energy who have had their preliminary training in those studies which encourage precision, and which lead to the development of our tactile, visual, and auditory senses.

Coincident with this idea are the views recently expressed in England at a meeting of the General Council of Medical Education and Registration. A special committee reported that the subjects for preliminary examination should include elementary mechanics of solids, and that the subject of hydrostatics should also receive attention. Anyone who has seen the average student wrestle with the problem of vascular pressure will not regard the last bit of advice as at all out of place.

Coming to the requirements suitable for a New York school, we should include some knowledge of Latin. This is pre-eminently the language of nomenclature. More recent derivations from other languages can generally be traced back to this one. The requirements in physics and mathematics as expressed in either of the schedules previously mentioned seem to us sufficient. Acquaintance with French or German, while vastly increasing one's acquaintance with the literature of the profession, cannot be regarded as absolutely necessary. Not out of place would be moderate requirements in those sciences which especially involve the doctrines of classification—as botany, natural history, and chemistry. Dr. Hodges places especial emphasis on biology and elementary physiology. They are most valuable preliminaries, and an accurate presentation of their principles necessitates no mean knowledge of English. Of course the requirements could not include simple mechanical drawing, but we regard it as a very decided help to the study of anatomy, and an accomplishment well worthy of cultivation by an aspirant for medical honors.

A NEW [illegible]

We are glad to chronicle the establishment of an institution distinctively for convalescents. A small institution has recently been opened by one of the sisterhoods of the Protestant Episcopal Church, near Stuyvesant Square. It is intended to receive those who are well enough to leave the large general hospitals, but who are not yet able to go to work. Working women needing rest, food, and possibly slight medical attention, will also be admitted. Those who pay for themselves will be charged six dollars per week. The principal support, however, must come from annual subscriptions and donations. An annual subscription entitles the contributor to one letter of admission, available for the current year, which can be given to any eligible patient, and will entitle the latter to a fortnight's stay in the Hospital. The name of the new institution is St. Andrew's Convalescent Hospital, and it is situated on East Sixteenth Street. The house of the sisterhood is at No. 233 East Seventeenth Street.

It is evident to anyone familiar with the hospitals of New York that our great present need is institutions similar to the foregoing. We have accommodation for all acute sickness, but the convalescents would be restored to health much faster if they could be conveyed to sanitariums instead of remaining in hospital. We need also a large institution for phthisis patients. Nearly every hospital now has its quota. They are treated in a routine manner, with cod-liver oil and cough-mixtures, while very little care is taken to study each case individually. A case of phthisis is usually voted a bore unless the chest is a museum of physical signs, when some interest is taken in it. If all these cases, or a large number of them, could be grouped in one institution, a more systematic study could be made of the clinical aspects of the disease. We have nothing in this country at all comparable to the Cousumptives' Home at Brompton, on the other side. Here is another opportunity for the charitably disposed.

CAN SYPHILIS BE TRANSMITTED TO ANIMALS?

One of the chief obstacles in the way of a better comprehension of the nature and pathogenesis of syphilis has hitherto been the impossibility of studying the disease otherwise than as it occurs in the human subject. Numerous attempts have been made to inoculate the lower animals, but without success, as they seem not to be susceptible to the action of the syphilitic virus. This fact has been made use of as an argument by divines and others, who maintain that the disease is a scourge sent to man in punishment for his sins; but it has been a source of discouragement and regret to those who seek to find out rather what syphilis is than why it is.

It is not beyond the range of possibility, however, that we may yet find some animal which shares with us the unenviable susceptibility to this affection. Dr. Sabater y Casals, in an article in the *Gaceta Médica Catalana* of May 15, 1886, says that he has seen two dogs, inoculated with the syphilitic virus, which presented symptoms very closely resembling, if not actually those of, the disease in question. There were the indurated ulcer at the seat of inoculation, the exanthem, the glandular enlargement, and, in one case, an almost unmistakably syphilitic affection of the nail. The differences between the symptoms exhibited by the dogs and those of syphilis in the human subject were only such as might be expected to exist, and as are seen, for instance, in malignant pustule when it attacks different species. Two cases are not sufficient to prove anything, but they serve to suggest the possibility that syphilis may be transmitted to some of the lower animals.

THE MORTALITY AMONG PHYSICIANS.

It is a well-established fact that the mortality among medical men is much above the average of that incident to most occupations. Dr. W. Ogle recently presented some interesting statistics bearing upon this point at a meeting of the Royal Medical and Chirurgical Society of London. He found that the mortality among English physicians for the three years from 1880 to 1882 was 25.53 per mille, while that of barristers was 20.23, and of clergymen 15.93. As might be expected, the infectious diseases found more victims in the medical profession than in other callings. Scarlet fever killed 59 out of a million physicians, while of adults in other pursuits only 16.01 died of this disease. The figures for diphtheria were 59 and 14 respectively, for erysipelas 172 and 136, and for typhoid fever 311 and 238. It is instructive to note, however, that the mortality from smallpox among physicians was many times below the average for non-medical adults, due, without doubt, to the greater care that medical men take to insure perfect protection by repeated vaccination. Pulmonary diseases are apparently less fatal to physicians than to others, for Dr. Ogle found that the number of deaths from this cause was twenty-seven per cent. below the average for the general adult population.

It is rather humiliating to find that deaths from alcoholism are more frequent among the members of the medical profession than among those of other occupations. Suicides are also more frequent, and what is worse, it is stated that medicine is the only calling among the members of which there is a steady yearly increase in the number of cases of self-destruction. It would be interesting to learn the cause of this increase, and whether it is dependent upon overcrowding of the profession and the consequent more bitter struggle for the means of subsistence. We suspect that the prevalence of both suicide and alcoholism may be traced, partly at least, to this cause.

A SPONTANEOUS CURE OF HERNIA.

The radical cure of hernia is a subject which has for centuries engaged the attention of surgeons, and the possibility of which is even yet, despite the great advances made in recent years, doubted by some. Undoubted cures are often obtained by Heaton's and other methods, yet spontaneous cures without operation sometimes occur, and perhaps more frequently than is generally supposed.

Several writers in *L' Union Médicale* have recently reported cases of this kind, some of which were a source of anything but joy and congratulation to the medical attendant. One of these is reported by Dr. L. Michalski. He was called to see a young man, who was said to have strained himself in dancing, and found a rather large inguinal hernia on the left side. He was unable to reduce it on the first trial, and three seances of taxis were required before the intestine was wholly replaced. Excepting this difficulty in reduction, the hernia presented nothing worthy of note, and the patient was dismissed wearing a truss. Two and a half years later the man returned to request a certificate in order that he might be relieved from serving in the army. Dr. Michalski thought a certificate unnecessary, but as he remembered the case well, gave it, neglecting to examine the patient again. At the medical examination, however, it was asserted that the man was sound, and fit for military duty. He then abandoned his truss and served out his term, without having any return of the hernia at the end of ten years.

Such a certificate, given in perfect good faith, might well have brought considerable trouble to the writer had he been unknown to the medical examiners, or had collusion with the conscript been suspected. The case is instructive, showing, as it does, that a hernia may not return after its reduction. And the possibility of such an occurrence should be borne in mind, not only by the surgeon in attendance, but also by those who may see the case afterward, and who may be led unjustly to accuse the former attendant of ignorance or something worse.

THE CAUSE OF CIRRHOSIS OF THE LIVER.

The cause of cirrhosis of the liver, of the common type, is uniformly ascribed to the use of alcohol, and the disease even has the name of gin-drinker's liver. In Germany one-third of the cases are attributed to brandy drinking (Thierfelder), while in England gin and brandy together share the opprobrium of setting up the disease.

While alcohol is always asserted to be the great cause, it is alcohol in the form of strong spirits which is believed to be most mischievous. For this reason the disease is said to be most common in North Germany and England, and less common in wine-drinking countries.

It is possible, however, that we may have to amend in some respects these conventional views as to the origin of cirrhosis of the liver. The disease was well known to the ancients long before distilled liquors were introduced. It occurs to a large extent in women, who comparatively rarely indulge in excesses with distilled liquors. In some years the number of deaths from hepatic cirrhosis, in this city, has been almost equally divided between males and females (105 and 93). The disease in this city has also increased in the past ten years about one-third, *i.e.*, from 0.6 per 1,000 deaths to over 0.9 per 1,000, while the increase in consumption of alcohol has been in the direction of fermented, not distilled, liquors.

In a recent article on "Alcoholic Cirrhosis," by M. Lancereaux, of Paris, who is well known for his studies regarding the effects of alcohol, he makes some statements which are likely to be regarded as heterodox. Alcoholic cirrhosis of the liver, he says, is not increasing in frequency (in France), while alcoholism is doing so. This is because alcoholism is due to the abuse of distilled liquors, cordials, etc. (an abuse which is increasing), while cirrhosis is due to an abuse of wine (an abuse which is not increasing). "Wine," continues M. Lancereaux, "is the most common and, perhaps, the only cause of the cirrhosis of drinkers, in France, at least." The proofs of this are: First, that cirrhosis is relatively frequent in wine-drinking countries, where alcoholism is rare; second, the almost absolute uniformity of a history of vinous excess in cirrhotics.

M. Lancereaux's statistics include 95 cases, all observed with the utmost care. These showed simple excess in the use of wine in 24 cases; excess in the use of wine and brandy, 63 cases; excess in the use of wine and beer, 1 case; excess in the use of wine and cider, 1; excess in the use of brandy, rum, or absinthe, 6.

The amount of wine used daily varied from two to six litres, the average being about three litres. The wine used was generally of a very cheap quality, and was mostly red wine. The other data regarding cirrhosis agree in the main with those of other observers. The age of greatest frequency was between forty and fifty, and there were 18 women to 77 men.

M. Lancereaux's statistics are most interesting in their relation to the subject of causation. His conclusions are certainly weakened by the fact that a large proportion of his cases (sixty-five) indulged excessively not only in wine but in brandy, and he does not say that the latter drink was not, after all, the favorite one. His claim, however, that cirrhosis is most common in wine-drinking countries is certainly worthy of attention, as it is quite opposed to current views. Thus Dr. Bartholomew, in his article upon Cirrhosis of the Liver in Pepper's "System of Medicine," states that the disease is not common in wine-drinking countries. In support of Lancereaux, it must be admitted that French pathologists were among the earliest and most active contributors to our knowledge of this disease.

A REVOLUTION IN THE AFTER-TREATMENT OF CATARACT AND IRIDECTOMY OPERATIONS.

We believe that it is only ophthalmic surgeons who, after operating, submit their patients to the horrors of the dungeon, obliging them, in the language of the contemporaneous drama,

"To lie in sodden silence in a dark, damp dock."

But there have now arisen certain gentlemen who have the boldness to decry this practice as unnecessary, and even hurtful. At the St. Louis meeting of the American Medical Association, Dr. Michel advocated the plan of using a light bandage to the eyes after cataract operations and iridectomies, and allowing the patients to be in a lighted room, where friends can come and read to them. Dr. Michel's plan was not favorably received at St. Louis, but it has been tried by Dr. Chisolm, of Baltimore, who reports fourteen cataracts and four iridectomies treated in this way. The method in detail is simply this: After the removal of a cataract or the performance of an iridectomy, the eyes if a cataract, the eye if an iridectomy, is closed in its normal position and a bit of isinglass plaster, about two and a half inches long by one inch wide, is then rendered flaccid by immersion in some germicide fluid and is neatly applied to the surface of the closed lids. When dried this forms a close, firm band. The patient is then allowed the full liberty of his room. In every case thus far operated upon by Dr. Chisolm the results have been uniformly good, and he has consequently abandoned the old method.

News of the Week.

The International Medical Congress.—The *Scottish Medical Journal* publishes editorially a letter from an American correspondent, concerning the International Medical Congress. The writer, after giving an account of the trouble, says:

"This democratic spirit has had full play, with the sad effect of alienating a majority of the men who, to an independent onlooker, must be regarded as essentially the representative men of the profession. It is useless for the present organizers of the Congress to comfort themselves with the thought that they have filled the places of the 'irreconcilables' with men equally good for Congress purposes. A comparison of the officers of sections named by the original committee with those finally selected by the present committee affords a most painful contrast; and the notable absence in every section of the men most prominent in American medicine will strike even the casual observer. The great cities of the East, Boston, New York, Philadelphia, and Baltimore, will not be represented scientifically, for, with two or three exceptions, the leaders and workers will hold aloof. Austin Flint, Jr., Lewis Sayre, and Lewis Smith, of New York, are the only men of first rank to represent the East in the present Congress. A list of those who are 'out' will embrace the men best known in Europe as American writers and workers, such as Bigelow, Bowditch (H. J.), Bowditch (H. P.), Holmes, Warren, Chadwick, and Homans, of Boston; Delafield, Draper, Dalton, Loomis, Seguin, Sands, Markoe, Jacobi, Lusk, Barker, and Lefferts, of New York; Stillé, Da Costa, Pepper, Bartholow, Goodell, Gross, Weir Mitchell, Agnew, Ashhurst, Wood, and Leidy, of Philadelphia. It has been a struggle of the West and South against the North and East, and the West and South have won."

Mississippi Valley Medical Society.—A partial programme of the Twelfth Annual Session of this Society, to be held at Quincy, Ill., July 13, 14, and 15, 1886, is as follows: Surgical Treatment of Hypertrophic Nasal Catarrh, W. C. Pipino, M.D., Des Moines, Ia.; A Case of Obstruction of the Bowel, Thomas D. Washburn, M.D., Hillsboro', Ill.; The Discovery of Anæsthetics, H. N. Lyman, M.D., Chicago, Ill.; Albuminuria and Disease of the Kidney, B. M. Griffith, M.D., Springfield, Ill.; Is the Pneumatic Cabinet a Practical Failure? H. J. B. Wright, M.D., Olney, Ill.; The Therapeutics of Bismuth and Asclepia Tuberosa, Amos Sawyer, M.D., Hillsboro', Ill.; Enterocolitis of Children, A. J. Steel, M.D., Charlestown, Ill.; Eti-

ology of Chorea, Frank R. Fry, M.D., St. Louis, Mo.; Neuro-retinitis Albuminurica, William Cheatham, M.D., Louisville, Ky.; Heart Failure, W. W. Fuque, M.D., Memphis, Tenn.; Intestinal Obstruction, J. H. Luckett, M.D., Owensboro', Ky.; Peritonitis, Andrew Seargent, M.D., Hopkinsville, Ky.; Operative Interference in Inflammation of the Knee-joint, A. R. Jenkins, M.D., Henderson, Ky.; Yellow Fever in Brazil, Preventive Vaccination, Frinxe's Method, Personal Observation on the Ground; Beriberi on the Coast of Brazil, Personal Observations, both by Horace M. Lane, M.D., Brazil, S. A.; A paper, by William Porter, M.D., St. Louis, Mo.; Surgical Treatment of Pleuritic Effusions, William A. Byrd, M.D., Quincy, Ill.; Artificial Alimentation, I. N. Love, M.D., St. Louis, Mo. Those in attendance will be returned at one-third fare by showing a certificate of having paid full fare coming. This is not a delegate body, but admits to membership, simply by registration, all practitioners in good standing. A cordial invitation to be present is extended to all members of the profession. Address Joseph Robbins, M.D., Chairman Committee of Arrangements, Quincy, Ill.

A Warning.—The Charity Organization Society begs to suggest to the physicians of New York City great caution in responding to appeals for assistance from one "Dr. Watson," who claims to have been a victim of the "Oregon" disaster. He is apparently near forty years old, tall, has thin face and dark complexion, Irish cast of features, and slight brogue. He exhibits a forged letter and gives a false address. He carries a list of several prominent physicians who appear to have given him sums of money.

The American Association for the Advancement of Science will hold its Thirty-fifth Annual Meeting at Buffalo, N. Y., beginning August 18th.

The Alabama Medical and Surgical Journal is the title of a new medical monthly, edited by Drs. J. D. S. Davis and W. E. B. Davis, of Birmingham, Ala. The first issue contains much interesting material, and shows excellent judgment in its arrangement. We are glad to see new journals starting in the Southern States. They are indispensable in developing the common interests of the medical profession of the States, as witness the good work done in Texas, Florida, and other localities.

Dr. Hunter P. Cooper, of Atlanta, Ga., lately of this city, has been made an adjunct professor of chemistry in the Atlanta Medical College. We congratulate the doctor and the College.

Medical Professorships.—Dr. L. Kirn, Extraordinary Professor in Freiburg, who had been elected by the medical faculty of Dorpat to the Professorship of Psychiatry, with charge of the clinic for mental diseases, has declined the invitation, preferring to remain in Freiburg. This can hardly be considered surprising, says *The Lancet*, if the rule which exists in Russian universities compelling professors to submit their lectures in manuscript to a police official several months before delivery is enforced in Dorpat, or at least in the medical faculty. There is, however, no doubt that professorships in Russian universities are not very comfortable posts at present, and that is the secret of numerous resignations which are so constantly being announced.

There is a Prospect of a new medical college being started at Colfax, Ia.

A Sensational Statement about Perambulators.—A somewhat sensational statement has been arrived at by the medical officer of the rural sanitary district of Hexham, in Northumberland, England, who, in explanation of the fact that 124 out of every 1,000 children in his district die before attaining the age of twelve months, asserts the mortality to arise from exposure of children in perambulators.

American Neurological Association.—The Council of the American Neurological Association announce that the regular business meeting of the Association will be held at Long Branch, N. J., on Wednesday, Thursday, and Friday, July 21, 22, and 23, 1886. Two daily sessions will be held, one in the morning from 10 A.M. to 1 P.M., and one in the afternoon from 3 to 5 P.M. A suitable room has been engaged at the Howland House, where the meeting will be held. A number of interesting papers have already been contributed, thus insuring the success of the meeting.

The International Medical Congress.—A committee of twenty-five members has been appointed in Vienna for the purpose of making arrangements for the forthcoming International Congress to be held here in 1887.

President Cleveland has consented to be one of the patrons of the Congress.

Suppression of Pain in Labor by the Local Application of Cocaine.—Dr. E. L. Partridge, of this city, writes: "Your editorial upon the 'Suppression of Pain in Labor by the Local Application of Cocaine' prompts me to a brief expression of views which, in the main, *dissent* from those quoted and endorsed (though not with great strength) by your journal. My experience is *wholly opposed* to the view that any relief can be obtained by the local use of cocaine previous to the passage of the head from the uterus. My view is based upon hospital observations and those of private practice which I have made. From a theoretical standpoint, I would also differ from the views quoted, calling attention to the fact that the pains of labor, up to the time of complete dilatation of the cervix, are in the ilio-inguinal and ilio-hypogastric nerves (belonging to the cerebro-spinal system), and that these pains are transmitted telegraphically, so to speak, by the irritation of the nerves supplied to the uterus and cervix (which belong chiefly to the sympathetic system). Now, it seems to me that there is one settled fact relating to the benefits conferred by the local use of cocaine, which is, that to secure them it is necessary to employ the agent directly to the nerves which have, or are to give, the sensation of pain, or to the immediate nerve-trunks, or nerve-centres. No applications to the cervix can accomplish this. I have never employed cocaine after the escape of the head into the vagina, nor shall I do so, for I am sure that chloroform can afford much more satisfactory moderation of pain; and in all cases where comparison might be instituted, the latter agent, intelligently administered, will be free from danger. I may add that I never use chloroform during the first stage of labor, relying upon chloral, or, rarely, morphine when any measures are required."

INDIANA STATE MEDICAL SOCIETY.—The following officers have been elected for the ensuing year: G. W. H. Kemper, M.D., President, Muncie; W. V. Wiles, M.D., Vice-President, Spencer; E. S. Elder, M.D., Secretary, Indianapolis; J. McLean Moulder, M.D., Assistant Secretary, Kokomo; C. B. Higgins, M.D., Treasurer, Peru.

THE INCREASE OF PHYSICIANS in New York and Brooklyn during the last three years is shown in the following table:

Years.	New York.	Brooklyn.	New York, Jersey, Connecticut.
1884-5	128	[illegible]	[illegible]
1885-6	113	57	[illegible]
1886-7	24	11	[illegible]

The decrease in the annual increment of New York City would be striking if the figures were trustworthy.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION has had an excellent record and has taken a place among the leading societies of the country. In the last year or two it is reported to have dropped off a little in activity, and at the last meeting of the American Medical Association its delegates were not admitted because the society had never adopted the Code. We learn that the next meeting at Quincy, Ill., promises to be a most successful one.

THE PASTEUR INSTITUTE OF THIS CITY has got to work, and a boy, bitten some weeks ago "by a dog supposed to be mad," has been inoculated *secundum artem*.

PROBABLY AN IMPOSTOR.—We think it just to warn the members of the profession in New York against a man who says he is a physician from the West, passing through the city on his way to visit his dying mother. He called on several physicians on Monday evening to beg a loan on a check, saying that he had lost his pocket-book, containing a sum of money and some certified checks, and that it was absolutely necessary for him to leave on the 11.30 P.M. train in order to see his mother alive. On Tuesday evening he called on others, alleging that he must leave the city on the nine o'clock train. Our suspicions may possibly be unjust to an unfortunate man, but it will do no harm to warn physicians against loaning money to any stranger who can give no better security than a check on an out-of-town bank.

HEN'S BLOOD IN THE TREATMENT OF ANÆMIA AND CHLOROSIS.—It is not easy to take seriously the claim of Dr. Francesco Brancaccio, of Naples, that the blood of the domestic fowl is an efficient remedy in pernicious and simple anæmia and chlorosis. Dr. Brancaccio, however, reports in detail eight cases to substantiate his opinion, two of these being of primary anæmia. All were first thoroughly treated with the ordinary remedies—iron, arsenic, quinine, and oxygen, but with no success. Hen's blood was then given in doses ranging from eighty to two hundred grammes daily. Examinations with the globulimeter were made to determine the diagnosis and progress of the disorder.

CREDIT TO WHOM CREDIT IS DUE.—The *Weekly Medical Review* is a wide-awake and progressive journal, but it makes a mistake in crediting the *Therapeutic Gazette* with an article on the "Diagnostic Test for Typhoid Fever," which appeared in the editorial columns of THE RECORD of May 22d.

CHRONIC DEFORMING RHEUMATISM—RHEUMATOID ARTHRITIS.—Many authors have of late years considered this to be a neuro trophic disease. Now, MM. Pitres and Vaillard announce that in two typical cases they found extensive and profound multiple degenerative neuritis.

KAVA KAVA IN GONORRHŒA.—Dr. H. C. Rogers, of Brooklyn, N. Y., writes: "I beg to avail myself of the medium of your journal to answer various letters addressed to me by gentlemen in reference to my paper 'On the Use of the Fluid Extract of Kava Kava in Gonorrhœa,' published in THE MEDICAL RECORD of May 8, 1886. I do not think that kava kava controls the disease as quickly as cubebs or copaiva, when they are taken at regular intervals for several successive weeks. There are few patients, however, who can take these medicines regularly, for even a brief period, without having their stomachs rebel, and thus becoming victims to nausea, eructations, vomiting, and anorexia. The consequence is that the medicine is taken very irregularly, or not at all. In nearly two hundred cases where I have used the fluid extract of kava kava, I have not seen or heard of a single case in which the medicine produced any unpleasant stomach symptoms, nor am I aware of any instance where it impaired the appetite. In fact, many of the patients informed me that it increased their desire for food. I wish to add that the cases mentioned in my paper as treated 'at the hospital' were of those in the out-door department of the hospital, as distinguished from those treated in private practice. In regard to both these classes of patients, I venture the opinion that the average duration of the disease would have been somewhat less had my instruction respecting the disuse of alcoholics been more strictly observed."

AT A DINNER GIVEN TO DR. WILLIAM H. PANCOAST on his retirement from the Chair of Anatomy in Jefferson College, he said that he had accepted the Chair of General Descriptive and Surgical Anatomy and Clinical Surgery, in the Medico-Chirurgical College of Philadelphia, an institution which is working out the problem of higher medical education by establishing preliminary examinations and a three years' graded course. This college, he said, had just purchased a commodious property near the centre of the city, and when the alterations were completed the Philadelphia Dental College, the Charity Hospital for Skin-diseases, and the School of Anatomy would unite with the Medico-Chirurgical Hospital and College in furthering the great and important work in which they are engaged. The dinner is described as beyond anything "since the dinner given to Professor Gross." We are at a loss to understand why among the guests there are mentioned none of the Jefferson College Faculty, or so few of the names of Philadelphia's well-known physicians.

Reports of Societies.

KENTUCKY STATE MEDICAL SOCIETY.

Thirty-first Annual Session, held at Winchester, Ky., June 23, 24, and 25, 1886.

WEDNESDAY, JUNE 23D.—FIRST DAY.—MORNING SESSION.

THE meeting was called to order by the President, J. P. THOMAS, M.D., of Pembroke. The minutes were read and the reports of the Committee on Credentials, the Committee of Arrangements, the Librarian, Secretary, and Treasurer, received and adopted. The amount in the treasury was $183.60. The report on necrology included the names of Drs. R. W. Dunlap and A. R. McKee, both of Danville.

Then followed

THE PRESIDENT'S ADDRESS.

He took for his subject "The Best Doctor for the Commonwealth, or the Doctor as an Officer of State." After a few remarks laudatory of the Society and its work he launched into the question of a higher medical education. He referred to the poor results attained in his own State, but was gratified at the work done in Alabama, Illinois, North Carolina, and Virginia. He would not compel, or even advise, the embryo doctor to waste his time in the

STUDY OF THE CLASSICS,

but endeavor before entering upon the study of medicine, to get a good English education, supplemented with all the knowledge of the natural sciences possible, especially chemistry and physiology.

The National Government is very strict in the selection of her medical officers. Why? Because she cannot afford to place incompetent medical men in charge of the lives of her soldiers and sailors. Why not the same solicitude as to her citizens? There are stringent rules as to the government of railroad engineers, because human life is constantly dependent upon their skill. Why not as strict laws regarding the education and training of medical men and women, who are also the guardians of the lives of the people? The present law in this State is utterly useless and inoperative and should be erased from the statutes.

The only way to get

PROFESSIONAL AGGRANDISEMENT

is by the co-operation and zeal of its members; whatever the doctors unitedly want they can get. Our greatest enemies are in our own ranks and camp. Why is it that our Legislature constantly shows more willingness to appropriate sums sufficient to stamp out disease in animals than to protect the health and prevent disease in the people. Two thousand five hundred dollars per annum is reluctantly granted our State Board of Health to crush out and prevent epidemic disease among the people of the entire State, and $6,000 voted from the treasury to stamp out a single disease in a single locality and among a single herd. The wonder is that the Kentucky State Board of Health has been able to accomplish what it has with the amount of money at its disposal.

DR. M. F. COOMES, of Louisville, then made the report on "Ophthalmology."

DR. J. G. CARPENTER, of Stanford, reported a case of

ULCERATION OF THE SIGMOID FLEXURE OF THE COLON.

It occurred as the sequel of dysentery. The patient was a male, aged twenty, American, good family history and constitution. Case seven months in duration. He elevated the trunk to seventy or eighty degrees, retracted the anus with a Sims speculum, inflated the bowel, used at different times sunlight, lamplight, and the electric lamp, and laryngoscopic mirror. He could see within the bowel twelve inches by measurement. To cleanse the bowel he used water as hot as could be borne. On looking up the literature the reporter found that Sims had reported a similar case in "Bryant's Surgery." This hot water was used twice daily for cleansing and antiphlogistic purposes. Nitrate of silver was applied every six to eight days, of a strength of forty to sixty grains per ounce.

DR. PINCKNEY THOMPSON, of Henderson, thought the claims of the reporter impossible.

DR. W. H. WATHEN, of Louisville, thought it could be done.

DR. WILLIAM BAILEY, of Louisville, thought that the reporter had been "able to see farther into the subject" than anyone else.

Adjourned till 8 P.M.

EVENING SESSION.

DR. E. WILLIAMS, of Cincinnati, read one of his customary witty papers on

THE UNCOMMONNESS OF COMMON POLITENESS.

Why is politeness like small-pox and scarlet fever? Because it is contagious. Non-contagious politeness is malignant. Like common sense, common politeness is a scarce thing in the market. The address was received with laughter, applause, and a vote of thanks.

DR. D. S. REYNOLDS, of Louisville, made

THE REPORT ON PATHOLOGY.

In considering this new science which we call pathology he wished to instil a sort of scepticism which rejects as facts everything which cannot be clearly demonstrated. He stood to affirm that

TUBERCULOSIS IS AN INFECTIOUS AND CONTAGIOUS DISEASE,

disputed by no one who has undertaken experimental investigations. Heredity, he thought, had nothing to do with it. He reported cases where he had found tuberculous bacilli in catarrh of the nose and ear. He reported, also, his examination of water from typhoid-fever wells in Louisville, and exhibited microscopical specimens.

DR. F. C. WILSON, of Louisville, thought heredity had much to do with the production of tuberculosis. He thought many cases could be traced to contact.

DR. PINCKNEY THOMPSON, of Henderson, thought that the specific cause of typhoid fever had not been discovered. In the city it is impossible to find a case which cannot be traced to some other case. In the country he had seen typhoid fever exist where it was impossible to have come from another case.

DR. WILLIAM BAILEY, of Louisville, objected to some of the positive assertions made in the paper. To him

THE GERM THEORY IS THE MOST PLAUSIBLE ONE.

Most theories must, as yet, be held *sub judice*. He thought we could not dismiss heredity with a wave of the hand, and was sure that we could not make the insurance companies dismiss heredity from their questions.

DR. J. T. WHITTAKER, of Cincinnati, said that in discussing the acquisition or

HEREDITY OF TUBERCULOSIS

we should inquire, Is there not more than one element in this disease? Disease requires not only seed, but soil. We might inherit the soil in which the disease would develop. The whole question hinges upon inoculability. This is proven. Introduce bacteria into the eye and you can see every stage of its development. If the disease is inoculable it must be contagious. Thirty per cent. of us die of it. Most of us recover, as is shown by the presence of tubercles post-mortem. The seed had not fallen in suitable ground. There is no disinfectant like ventilation. We use horrible disinfectants, are [illegible] obliged to open the windows, and thus get ventila-

tion. We should destroy the sputum by burning, or expectorate into a jar containing bichloride solution. In Germany they separate tuberculosis cases from others. Here there is a great hue and cry if small-box is exposed in the ward. Yet tuberculosis is so exposed every day. It is a question whether a child ever inherits any disease from its father. Pneumatic differentiation, he thought, had entirely changed the prognosis of tuberculosis. The ventilation of the lungs is the great thing. He did not wish to be quoted as saying that this was a sure cure for consumption. The best method we had was to secure ventilation of the lungs. No spray will destroy all of the bacilli. It cannot reach them all. This pneumatic treatment is not as good as a mountain-top, yet it is the next best thing. I do not think everyone who has tuberculosis must die.

Dr. J. N. McCormac, of Bowling Green, thought that if it was true that micro-organisms are given off which are dangerous to persons in the room, we are guilty of criminal neglect in not acting accordingly. He spoke of the action of the National Board of Health at its recent meeting; spoke in favor of the disinfecting of typhoid-fever stools, and said there was no one here who did not believe that THE FIRST CASE OF CHOLERA, if found, could be stamped out. He referred to Sternberg's investigations of disinfectants, which he said were only deodorizers and delusions. He favored the use of the bichloride.

Dr. E. R. Palmer, of Louisville, thought that the feature most worthy of discussion was that bearing on heredity. He thought the pendulum had swung too far. He agreed with Dr. Whittaker that the father could not transmit a specific taint. He might transmit an inherent weakness. We are probably all constantly inhaling tuberculous germs, but they do not find the proper soil. The father may transmit to his offspring certain conditions of body, which may be followed by tuberculosis. He thinks, with Dr. Otis, that unless the father syphilizes the mother, he does not syphilize the offspring.

Dr. T. A. Reamy, of Cincinnati: So long as the wife is not pregnant she is safe, unless mucous patches or sores are present. He had known the father to propagate the disease ten years after the disappearance of all symptoms.

Dr. D. S. Reynolds, in closing the discussion, said he assumed that no one except those gentlemen who have not undertaken investigation will assume that tuberculosis is due to one cause. It is well known that many persons inherit so-called strumous diathesis. The point in relation to the transmission of tuberculosis by the father has been settled. The father cannot transmit to the offspring anything except tendency to form. He cannot transmit direct disease. The principal point is, What shall be done to prevent this disease? Answer, The destruction of the media by which it is transmitted.

The Committee on Nominations reported the following

NAMES OF OFFICERS

for the ensuing year, who, on motion, were declared elected:

Dr. W. H. Wathen, of Louisville, President; Dr. J. M. Harwood, of Shelbyville, Senior Vice-President; Dr. J. H. McKinley, of Winchester, Junior Vice-President; Dr. J. Steel Bailey, of Stanford, Permanent Secretary; Dr. F. C. Simpson, of Bardstown, Assistant Secretary; Dr. Edward Alcorn, of Hustonville, Treasurer; Dr. J. G. Brooks, of Paducah, Chairman Committee of Arrangements; Drs. D. S. Reynolds, of Louisville, A. W. Willis, of Winchester, A. Sargent, of Hopkinsville, J. H. Letcher, of Henderson, W. E. Poynter, of Midway, J. W. Harwood, of Shelbyville, Board of Censors.

The next place of meeting will be Paducah, the third Wednesday in June.

The newly elected President was conducted to the chair, and made a few remarks, after which the Society adjourned till 8 A.M.

THURSDAY, JUNE 24TH—SECOND DAY—MORNING SESSION.

Dr. J. N. Irvin, of Louisville, made the

REPORT ON THE PROGRESS OF THE PRACTICE OF MEDICINE.

He discussed tricuspid regurgitation, tubing of the larynx for croup and diphtheria, intra-uterine injection for the purpose of producing premature delivery, fatal results of these injections, the mechanical theory of inflammation, and the importance of inflammation producing the pyrexia of many fevers.

Dr. J. T. Whittaker, of Cincinnati, thought that tricuspid regurgitation reveals itself by a bruit a considerable time before pulsation in the neck is observed. The earliest sign is an increasing tension of the radial artery and hypertrophy of the left heart.

INTUBATION OF THE LARYNX

has been pointed out as feasible in the treatment of diphtheria and croup. My experience has been inevitable failure. I resort to tracheotomy. This is done so easily and readily by the surgeon now. He dwelt especially on that class of cases having crowing respiration. Rickets, he said, were very much more common than generally supposed. This spasm of the larynx calls attention to rickets. Diarrhœa is most common in these children, alternating with constipation, often sweating and restlessness make up the diagnosis in the earlier stage of the disease, after which come the enlarged ends of bone, the roseola, the deformities of the pelvic, and other bones. We should treat rickets early. It needs only treatment to be relieved. Cod-liver oil and phosphorus are the remedies. Write as follows: Phosphorus, one-seventh grain; emulsion of cod-liver oil and gum-arabic, two ounces. The laryngismus stridulus disappears with the disease.

As to pyrexia—we are about to undergo great change in the treatment of fevers. We have been taught to subdue fevers at all cost. This view is changing. It is pretty well settled that typhoid fever is due to a specific cause. It would seem that nature's method of attenuating virus is by elevation of temperature. It may be that we are taking away this very method of nature to relieve herself of trouble, and we are not justified in resorting to extreme methods of antipyresis.

Dr. William Bailey, of Louisville, thought that intubation of the larynx had proven successful in the hands of those who had used it. He thought croupous pneumonia not simply an essential fever, but there was something back of that. He thought these fevers quite different from those of boils and abscesses. They take a typical course.

Dr. J. A. Larrabee, of Louisville, spoke

REGARDING RICKETS.

He thought the prevalence of the disease had increased. The trouble is, it is not recognized until the elaborations and distortions show that the disease *was* rickets, not *is* rickets. So many children are thrown upon the world, like Romulus and Remus, to be brought up on the modern wolf—the feeding-bottle. The origin of the disease he believed to be in the intestinal canal. Phosphorus is of less use than the care of the intestinal canal. Hygienic surroundings are all-important. The principal means of treatment are not found in the apothecary's shop. Fresh air, food, and exercise are required. This is one of the most important diseases in infantile practice.

As to intubation, I have been enlightened. I had been somewhat drawn toward it, but had no practical experience.

Dr. M. T. Scott, of Lexington, made the

REPORT ON THE PROGRESS OF SURGERY.

He first discussed abdominal surgery and thought true conservatism consisted in saving the lives of our patients.

He spoke laudatorily of Kentucky's patron saint, McDowel, and considered his boldness, sagacity, and success no less worthy of admiration and praise than the 135 consecutive, complete, and successful ovariotomies of Tait. He next considered the advisability of abdominal section for traumatic peritonitis. Tait, for years, has not allowed a patient to die from acute peritonitis without extending the chances of recovery offered by abdominal section. He has operated on 44 such, all but 3 recovering. Owing to modern improvements in firearms, visceral lesions will in all probability be vastly more frequent than formerly. Laparotomy for perforating wounds has the following objects: 1, To establish diagnosis; 2, to repair breaks in the continuity of the organ; 3, to arrest hemorrhage; 4, to remove extravasated and extraneous matter.

Gastrotomy as a means of removing foreign bodies and locally treating the stomach is now recognized as justifiable. He referred further to duodenostomy, surgery of the spleen, liver, gall stones, cholecystotomy, operations on the kidney, spleen, and bladder—also to the action of cocaine on the genito-urinary tract. This remedy, he thought, lessened the calibre of the urethra.

AS TO ALEXANDER'S OPERATION,

he thought that careful gynecologists would decide with Emmet that as much good can be accomplished without subjecting the patient to such questionable risks.

Dr. D. W. Yandell, of Louisville, complimented the paper highly. He found little room for discussion, but wished to speak on one point, the difference between

STAB AND SHOT WOUNDS,

of which we unfortunately see so much in Kentucky. The size of the ball is of first importance. I think Otis' statement with regard to Minié balls correct, viz., the man who gets a Minié-ball through the small intestine dies. The small six-shooter, especially the Smith & Wesson, often causes injuries which we can reach. Hence I always inquire, when called to a shot injury, was it a Smith & Wesson? The principal question is that which relates to symptoms. Shot-wounds cause more or less shock, as to the nature of the wound, the individual, and the circumstances of their occurrence. To say that in all shot-wounds which enter the belly we should open the abdomen, is a very loose statement. I would say in either shot or stab wounds, open no belly unless there are symptoms demanding it. These symptoms, if going to occur, are generally present by the time you have reached the patient. Men are not shot down by your side. In shot-wounds, unless there are symptoms on the part of the pulse or temperature that there has been injury to some viscus, I do not open the abdomen. I would make the abdominal cut large enough to see every possible danger. As to cocaine in cystitis and operations done on the urethra, I have been disappointed.

Dr. J. G. Brooks, of Paducah, reported a case of

LAPAROTOMY.

A lad, aged eleven, was stabbed in the abdomen with a Barlow knife. A large piece of intestine protruded. He was found pallid, vomiting, and nearly pulseless. On consultation it was decided to open the abdomen. The boy was thought to be dying. An incision was made in the median line; on opening the peritoneum a pint of blood spurted out. A brief search revealed a wounded vessel in the mesentery, which was tied, the cavity cleansed, the intestine washed with warm antiseptic water and returned. Brandy was given hypodermatically. No sponges were at hand. The operation was made on the bed and by lamplight. Fortunately the most elegant operations do not always result most elegantly. The third day the patient sat up, and the tenth day attended court and testified. The sixth day the sutures were removed and the wound found healed. A considerable amount of blood was allowed to remain, but was fortunately readily absorbed. The propriety of this and the propriety of keeping the stab-wound open might be questioned. Had the operation been adverse, the lawyers at trial would probably have said the doctor, not the knife, killed the boy.

Dr. J. N. McCormac, of Bowling Green, would have commended the operation had it been adverse in result. He reported a case in which, nine years ago, he had removed eleven inches of the small intestine for gangrene.

Adjourned till 2 P.M.

AFTERNOON SESSION.

Dr. D. T. Smith, of Louisville, read a paper on

SOME MOOT POINTS IN THE MECHANISM OF LABOR.

The points discussed were, the cause of head presentations, the physics of expulsion, and the mechanism of rotation. The doctor believed that the great preponderance of head presentations is induced by the effects of swimming movements upon animals in water in connection with the changes undergone by the uterus during gestation. A man in water not using the arms, but making natural movements with his legs, is drawn head foremost to the bottom. The child in the womb scarcely uses its arms, and the movements of its legs cause it to take the position head downward. In the latter months of pregnancy, the uterus being conical in the lower segment, the child is retained in that position. The animal, on the other hand, swims by its natural movements upward to the outlet. The mechanism of expulsion has for its object the changing of the uterus from the spherical to the cylindrical form, and thereby the most economical reduction of its capacity. Hence the development of the circular band of fibres around the middle of the organ and the arrangement of muscular contraction which causes the body of the parturient to curve forward. The essayist was of the opinion that the reflexes from the lower segment of the uterus are conveyed to the dorsal and abdominal muscles instead of its own muscles. He doubted if the iliac and psoas muscles are greatly contracted during labor.

In rotation he inclines to think that the fact that the face and forehead are more angular in outline and are also smoother and more easily freed from vernix, has a share in determining rotation. This condition increases on the passage of the face. This feature, the essayist suspected, might exert a very decisive influence in rotation from right to left occipito-posterior positions to occipito-anterior positions.

Dr. J. M. Harwood, of Shelbyville, read a paper on

THE THIRD STAGE OF LABOR.

In this paper he advocated the immediate removal of the placenta and recommended the same treatment in cases of retained placenta.

Dr. W. H. Wathen, of Louisville, thought this was a subject to which the physician pays too little attention, believing that nature will attend to it, and she usually will. So may an ignorant midwife in a majority of cases; yet there are others which require scientific knowledge, and without scientific knowledge children and women are permitted to die. The dangers are

HEMORRHAGE AND SEPTICÆMIA.

He considered first the question of hemorrhage. To prevent this, the moment the child is born let your hand follow down the uterus. Keep your hand over it, above the symphysis pubes, and watch that the uterus does not relax. If it is contracted, let nature have an opportunity to expel the placenta. If not, use gentle friction.

Dr. J. G. Cecil, of Louisville, did not agree with the essayist in his views as to traction on the cord. He described, minutely, Crede's method. He did not think it best to hurry too much in expressing the placenta. We owe some duty to the child. It has been proven that

the early tying of the cord robs the child of from one to three ounces of blood. As one-ninth of the child is blood, and if the child weighed seven pounds, this amount —12.33 ounces—would be felt. He believed Crede's method the best method to prevent hemorrhage. He would defer separating the placenta till pulsation had ceased.

Dr. Turner Anderson, of Louisville, could not conceive of anything more hurtful than this

TELEGRAPHIC METHOD OF DELIVERING THE PLACENTA.

He thought that all practitioners, as they grow older, find fewer cases requiring the introduction of the hand into the uterus. In the earlier years of my practice I encountered more cases of retained placenta than since. This has diminished, till now a retained or adherent placenta, or hemorrhage, is one of the rarest things, and I am beginning to believe that they are occurrences which happen in our earlier practice. I advise to wait. My practice is to allow the patient to recover somewhat from the shock of the second stage. Unless there are contra-indications, I wait from fifteen to forty-five minutes. The patient by this time has recovered from the shock, and tonic contraction has set in. I prefer the method of Crede to all others where I am obliged to assist. I do not believe in introducing the hand when avoidable; not that I think a clean hand will cause any trouble.

Dr. T. A. Reamy, of Cincinnati, promised to discover no new thing to the Society, but wished to condemn the method of Crede in natural labor. The adoption of Crede's method throughout the country has been the cause of much more injury than good. You may just as well cut the cord at once as compress the uterus and expel the placenta. The latter stops the pulsation. Placing the hand on the abdomen is only for the purpose of making observations, not to contract the uterus. We never have hemorrhage when there is pulsation in the cord. While the cord pulsates you may rest easy.

POST-PARTUM HEMORRHAGE IS A GREAT BUGBEAR.

When the cycle is complete the uterus will contract. It knows how to contract; the idea of our teaching it how! True obstetric science is marvellous. Irregular contraction and retained placenta is often due to this compression. After the placenta is detached the pulse becomes weak and ceases.

Dr. Harwood, in reply, said that he had not found more cases of hemorrhage and retained placenta in the earlier years of his practice, but they increased as he grew older.

Dr. J. B. Marvin, of Louisville, made a clinical report on

PROGRESSIVE MUSCULAR ATROPHY,

in which he reported a case and dwelt on the incurability of the disease.

Dr. H. H. Grant, of Louisville, made the report on the

SURGERY OF THE GENITO-URINARY CANAL.

Dr. D. W. Yandell, of Louisville, instead of making the incision into the bladder with the scissors, uses the finger-nail. He cuts down on to the bladder, then lays aside the instruments and scratches his way into the bladder with his finger-nails. This method avoids all hemorrhage. He does not use stitching, but inserts the drainage-tube. Harrison's operation of perineotomy, he thought, would grow in favor.

Dr. Joseph Ransohoff, of Cincinnati, said that in 1880 he was called into Indiana to see a man who had been passing his water every ten to fifteen minutes. The parts were so sensitive that it was impossible to pass any instrument. The patient was put under ether, as we had not cocaine as yet.

A PAPILLOMATOUS TUMOR OF THE BLADDER

was found, and perineotomy was done. In large, flabby persons, those who generally have enlarged prostates, the perineum is very long. He related a case where his patient died in twenty-four hours after he removed two quarts of urine by the catheter. The patient suffered more from his successful introduction of the catheter than from the unsuccessful attempts of his predecessors. He died from shock, as one does from the removal of too great an amount of ascites at one time. He did not favor delay in operating in prostatic enlargement.

Correspondence.

OUR LONDON LETTER.

ELECTROLYSIS IN THE TREATMENT OF URETHRAL STRICTURE—CONTAGIOUS AND [illegible] FEBRILITIES—TESTS FOR ALBUMEN—ANÆMIA—THE NEW ACT AFFECTING MEDICINE—EXTRA-CANONICAL INFLAMMATION—SEXUAL SERVICES RENDERABLE—DEGREES TO FOREIGN MEDICAL STUDENTS—THE MEDICAL COUNCIL AND THE VISITATION OF EXAMINATIONS—STATISTICS OF PNEUMONIA—THE MEDICAL BILL AND THE REGISTRATION OF FOREIGN MEDICAL DEGREES.

[illegible], June 21st, 1886.

At a recent meeting of the Medical and Chirurgical Society an interesting paper, by Dr. Steavenson and Mr. Bruce Clarke (both of St. Bartholomew's Hospital), was read. The subject of it was "The Treatment of Stricture of the Urethra by Electrolysis." They maintained that their results bore out in every particular those reported by Dr. Newman, of New York. The negative pole of the battery was applied within the urethra. The electrolytic action could be limited to the points touched by the electrode, as the current need not be passed until the apparatus was *in situ*. No anæsthetic was used and they had found but little pain to be caused, and usually no hemorrhage. The authors suggested that for parts difficult of access, such as the male urethra and the uterine cervical canal, the use of electricity might be advantageously substituted for that of ordinary caustics. Eschars produced by caustic alkalies were said to heal with less contraction than wounds otherwise caused, and electrolysis with the negative pole of a battery was a means of applying the same destructive action as that caused by caustic alkalies to parts difficult of access by other agents and methods.

In the discussion following the paper Messrs. Berkeley Hill, Swinford Edwards, and Buckstone Browne took part, and expressed a guarded approval of electrolysis as a therapeutic agent in dealing with urethral stricture. The general opinion of the speakers seemed to be that the cases operated on were as yet too few, and the time which had elapsed too short, for a final opinion to be expressed on the subject—a view which was shared by the authors themselves.

Some discussion has taken place respecting consultants, general practitioners, and their mutual relations. A good deal of jealousy apparently exists, for the existence of which something may be said on both sides. Among consultants, specialists are apparently the greatest sinners. I have heard of a specialist who, in taking sole charge of a patient to operate on him, gave as a reason for excluding the general practitioner in attendance, that it was no part of his duty to teach his own specialty to the latter. I hope and believe that such instances are not of common occurrence. Still, it is undeniable that some consultants are apparently only too ready to take entire charge of patients who have really been sent them simply to obtain an opinion—not to place themselves under them for a course of treatment. The question has, of course, like most others, two aspects. I have heard consultants remark that some general practitioners would never send their patients to a

physician or surgeon until they were obliged to, but kept them in hand as long as they could themselves.

At the last meeting of the Clinical Society the report of the Albumen Test Committee was presented. In this the various tests were reviewed. Nitric acid was pronounced to be, on the whole, the most reliable and delicate. Those practitioners who have gone on using it, and have been too conservative to adopt any of the numerous new tests introduced within the last few years, may therefore now have the satisfaction of feeling that they are, after all, quite abreast of modern science. Dr. Oliver's urinary test-papers received a well-deserved commendation for their portability and delicacy of reaction. The committee also reported favorably on Dr. Johnson's picric-acid test, Dr. Pavy's pellets (ferrocyanide of potassium and citric acid), the potassio-mercuric iodide test, and Sir William Roberts' acid-brine test.

At the same meeting of the Society Dr. Caton, of Liverpool, read notes of a case of aneurism of the hepatic artery. Only ten cases of this affection had, he said, been previously placed on record. In Dr. Caton's case the aneurism was not diagnosed during life.

Dr. Hale White read a paper on a case in which simultaneous inflammation of several serous membranes occurred. The patient was a girl of nineteen. She had never suffered from rheumatism. Peritonitis, pericarditis, pleurisy, and endocarditis all occurred. Recovery ensued.

A special meeting of the Metropolitan Counties Branch of the British Medical Association was held on Monday last, to consider the question of medical degrees for London students. The chair was taken by Dr. Walter Dickson, President of the Branch. Speeches in favor of the movement were delivered by Sir Andrew Clark, Mr. Jonathan Hutchinson, Mr. Macnamara, Drs. Habershon, Moxon, Broadbent, Sansom, and the chairman. The following resolution was moved by Sir Andrew Clark, and carried with only one or two dissentients: "That negotiations with the University of London not having led to the desired result, this meeting recommends that the Royal College of Physicians of London and the Royal College of Surgeons of England be requested to endeavor to obtain power to grant degrees in medicine." A circumstance which cannot but have contributed largely to concentrate professional attention on this subject has been the increase of late years in the number of students going north. I do not mean to say that the entries in all the London schools have absolutely decreased, but they have most decidedly not gone on increasing as they would have done but for the exodus northward. Students are finding out that practically they can, by going to one of the Scottish universities, obtain a degree in as little time as it takes them in London to get the ordinary diplomas. They may have to work a little harder, but they have the stimulus before them of a greater reward, and modern medical students are by no means so devoid of industry as those would think whose sole acquaintance with them is derived from the pages of Dickens. The "Bob Sawyer" type has for the most part disappeared. Needless to say, the stationary state of the entries at the London schools has proved a powerful stimulus to London teachers to take up the degree question. The argument to the pocket is a very powerful one, and has, to say the least, proved a powerful adjuvant to more worthy motives.

The recent meeting of the General Medical Council has been, if not very instructive, at any rate amusing. Dr. Haughton, of Dublin, moved a resolution that it was desirable to visit and report on the methods of teaching required by the licensing bodies. Dr. Matthews Duncan, in seconding the motion, sounded the praises of the lecture system, and maintained that a man would learn midwifery better in three months by attending lectures than in two years from a book. "The *viva voce* lectures of a good teacher," he said, "would always be valuable." But unfortunately all teachers are not good, and those who are condemned to sit and listen to lectures from bad lecturers will be tempted to echo Dr. Quain's remark that he had "no faith in lectures." Dr. Struthers, of Aberdeen, defended the lecture system, and also the Scotch plan of teachers being also examiners. No system of examination, he maintained, could be complete in which the teacher did not take part, and he would rather sell stamps in a post-office than be a teacher under those circumstances. Dr. Struthers wound up a very laudatory account of the Scotch system by referring to the slight remuneration of Scotch teachers. Mr. Rawdon Macnamara satirically remarked on Dr. Struthers' omission to refer to Scotch modesty, and Dr. Haldane said that, as for the moderate incomes of Scotch teachers, why, some of them were making three or four thousand pounds a year. Dr. Haughton's motion was carried, as was also a resolution that visitors be appointed by the General Medical Council to visit the several medical schools and report upon their methods of teaching.

Some lively discussion took place on the presentation of the report of the committee who had visited the final examinations of the universities of the United Kingdom. Much of the report will certainly excite surprise. Oxford has the repute of being sufficiently lenient in its medical examinations, but got off with very slight censure. The classical paper was condemned, and the examination in surgery was deemed insufficient. At Cambridge, which is generally belived to be more exacting in its medical examinations, both surgery and midwifery were condemned. Durham was favorably reported on, which certainly seems rather anomalous after the censure passed upon what have been believed to be severer examinations. The medical degrees of the London University have long been regarded as the most difficult to obtain of any in the kingdom, but their arrangements have met with unsparing criticism. The clinical examination in medicine and the examinations in medicine and surgery have been branded as not sufficiently searching. Dr. Quain defended the university, and admitted that oral examination might be extended, and that more surgery might be included in the M.B., but was it worth three hundred and seventy pounds to secure that, for that was what the visitation cost? Dr. Struthers rejoined that it was worth three hundred pounds to find the University of London out, for they had all been told to look up to it as a model institution.

The question of the teachers being also examiners was raised again in 'connection with the University of Edinburgh. The examinations in practical surgery for the Edinburgh degree were deemed unsatisfactory, and the absence of the laryngoscope and the ophthalmoscope from the examinations was remarked upon. Dr. Matthews Duncan said he disapproved of the uterine sound being used in the examination, as had been stated by the visitors to be the case. There was nothing to show that the same woman might not be subjected to the same operation by a succession of students. The University of Glasgow was favorably reported on. With reference to the University of Dublin, whose examinations have a high repute for severity, it was stated by the representative in the Council of the Royal University of Ireland (Dr. Banks) that if (at the University of Dublin) a man passed well in other subjects, but failed in one, he was put back, but not re-examined upon the subjects upon which he answered well. Dr. Banks remarked that it was a very hard thing for a man who answered well in clinical medicine and surgery, and who might fail upon some less important subject, to have to keep up his knowledge of minute anatomy, and be re-examined upon it at the end of another six or twelve months—an observation which examining boards in general would do well to bear in mind.

At the concluding meeting for this session of the Medical and Chirurgical Society, Dr. Angel Money read an elaborate paper on some statistics of pneumonia, referring especially to the relations of delirium and tempera-

ture. Dr. Money concurred with Heinze in the latter's conclusion that mere pyrexia has little to do in the production of delirium, but he admitted that prolonged pyrexia and high transitory fever must exercise a deteriorating influence on the nervous centres, and therefore predispose to delirium. From his investigations he had found that the number of cases with delirium was largest in those in which the highest temperature recorded was 104° and 105°. The presence or absence of delirium appeared to exert no influence on the mortality. The third decade of life (in cases where the temperature exceeded 104°) seemed most fertile in the production of delirium, but the largest number of cases of pneumonia occurred at that age and with that degree of fever.

Dr. Wilson Fox said it was important to recognize that delirium often set in with a falling temperature, and he opposed the wholesale adoption of the cold treatment of pneumonia.

Dr. Norman Moore discussed the causes of death in pneumonia, a prominent place amongst which he was inclined to give to emphysema. He considered the amount of exudation was a point of importance in relation to prognosis, and that this might be determined to a large extent by careful physical examination.

Dr. Moxon opposed Dr. Norman Moore's views as regards emphysema, and deprecated excessive physical examination, which might, he thought, have something to do with the causation of a fatal issue.

Dr. Oliver Wendell Holmes was one of the guests at the *conversazione* at the College of Surgeons, given by the President, on Wednesday last. Over thirteen hundred persons were present, and the museum was illuminated by the electric light. On the same evening he had previously dined with Sir Henry Thompson—Mr. Gladstone, Mr. John Morley, Mr. Browning, Sir James Paget, and others being invited to meet him.

The dissolution of Parliament being so near, there is but little chance of the medical bill passing, although Mr. Gladstone has promised it shall receive special attention. It has been so emasculated that, should it pass, the best that can be said of it is that it is not likely to do any harm. On the suggestion of Dr. Balthazar Foster, M.P., one very useful clause has been added, viz., one to permit the registration of foreign medical degrees obtained by British practitioners already registered. At present no foreign degree, however honestly obtained, can be registered, although the holder may already be registered in virtue of other qualifications.

OUR PARIS LETTER.

[From our Special Correspondent.]

Paris, June 24, 1886.

In the month of January last, Dr. A. Nicolas, formerly a surgeon in the French navy, was engaged by the Society of Public Works of Paris to proceed on a mission to the Isthmus of Panama, with a view to organizing the medical service of the Society, and at the same time to ascertain whether the Isthmus is as insalubrious as it has been reported to be, and if so, to make researches as to the cause or causes, and to suggest such measures as may be found necessary to extenuate the effects of the climate, and render the place habitable by the employés of the Society. Dr. Nicolas returned to Paris about three weeks ago, and soon after his arrival read his report before the Academy of Medicine, which is a most interesting document, but which, for want of space, cannot be reproduced here in its entirety. I may, however, mention that it is anything but encouraging to those who may have an idea to go thither in search of employment, or of locating themselves there, as I gather from the report that the climate at the Isthmus is as disastrous alike to Europeans or white races as it is to the natives or blacks. According to Dr. Nicolas, the prineipal cause of insalubrity is the amount of stagnant water about the place, and the pernicious influences peculiar to tropical regions, the prevailing diseases being hepatitis and dysentery among the whites, fevers, dysentery, and chest affections among the blacks. The whites are, of course, also subject to fevers, but nothing like in the same proportion as the blacks. In studying the etiology of these diseases, Dr. Nicolas does not hesitate to affirm that in the negro they are produced by cold, as it is well known that the power of resistance to climatic influences is not very great in them. The fevers most prevalent are intermittent, or the common paludal type, remittent bilious fever, and yellow fever.

The author avers that, for the first time in all his practice, he heard during his stay at Panama of cold being incriminated in the etiology of fevers, and during his sojourn of three months in that locality he learned by experience the confirmation of this assertion, for which he offers the following explanation: "The perspiration produced by the heat at Panama is more passive than otherwise; one is constantly plunged in a bath of wet linen, or, when one is naked, in a layer of water that does not evaporate; and one is obliged to perform ablutions and change one's clothes three or four times a day. The latter are hung up in the apartments to dry, which contributes to the dampness and coolness of the air in the rooms. This in its turn renders the body cold, which, added to the fatigue of the day and sleepless nights, reduces the power of resistance of the body, and causes it to become more liable to contract the fevers of the locality." Dr. Nicolas makes out that in all his travels he never experienced anything like the heat of Panama, though he has been in many places situated near, or on, the equator—not that the temperature is exceptionally high, but it is of a stuffy and enervating character. This enervation is manifested by the "powerlessness of cerebration" and blunting of the memory, as well as by sleeplessness, which condition is almost permanent and produces a state of cerebro-spinal irritability, followed by depression of spirits and its attendant evils. As regards the lassitude that is felt, the author suggests that the pathology of that resulting from fevers is identical with that attending fatigue, and that the state of the nervous tissue approaches to that of the muscles, which are loaded with the waste elements of the organism which the urine or the perspiration were powerless to eliminate. After painting the country in such sombre colors, Dr. Nicolas, in his patriotism, nevertheless recommends the undertaking now in progress at Panama to the consideration of his countrymen, "as it is a national work and the whole world has its eye thereupon."

Whatever may be the ultimate result of M. Pasteur's anti-rabic inoculations, M. Pasteur himself is being covered with honors, and money is flowing in from all sides for his institute. About a week ago he received a medal from the Humane Society of the Seine, which was handed to him at a meeting of the Society at the Sorbonne, and under the presidency of the Minister of Public Instruction. Several government functionaries and members of Parliament were present, and M. Anatole de la Forge, the well-known deputy, in presenting M. Pasteur to the Society in company with M. de Lesseps, expressed himself to the effect that these two illustrious men have deserved well, not only of their own country, but of the world at large, for their persevering exertions for the benefit of mankind in general, though the bent of their genius has been turned in different directions.

The subscriptions for the institute amount to this date to 1,194,182 francs, as shown by the official journal. This sum includes 400,000 francs voted by the French Parliament. The Paris Municipal Council, however, has not only displayed less generosity in a pecuniary way, but has also taken every opportunity of throwing a damp on M. Pasteur's efforts, as some of the members are somewhat sceptical as to the real value of M. Pasteur's discoveries.

INFLUENCING SEX IN UTERO.

To the Editors of The Medical Record.

SIR: From time to time communications appear on the topic of influencing the sex of a child *in conceptione*. It is a very old topic, and always an interesting one, though its solution is surrounded by many delicate obstructions that appear almost insurmountable. Its honorable study, in my judgment, is no more an impropriety than is the study of any other topic connected with the physiology of generation.

I have no new theory to present, nor any old one to defend. This, like any other problem in science, is not to be determined by theoretical opinions, except as such opinions are established by numerous facts which are in themselves accurate, without coloring, without contortion. Some facts that I have carefully collated during a practice of thirty-five years may be interesting.

Making the common-place observation that some parents had only girls, while others had only boys, I was prompted to seek for all attainable information as to circumstances or conditions that might influence the generative system to these results. In one family the following facts were obtained: Seven boys had been born and no girls. The wife died, the husband married again, and to him the second wife bore four girls and no boys. The two wives were nearly identical in build and temperament; the husband was a man of medium size and very healthy. This father was one in a family of four boys; the first wife was one in a family of five girls and one boy; the second wife from a family of two girls and three boys. The first wife habitually went to sleep early in the evening, on a sofa; awoke when her husband came from business, and retired with him about 10.30 to 11 P.M.; rose an hour or more before the husband in the morning, he being a late sleeper. The second wife was a great reader; seldom retired till after midnight, the husband having been in bed and asleep for an hour or more; and she commonly arose about an hour after the husband in the morning.

Knowing these circumstances, it occurred to me that cohabitation with the first wife probably took place when they retired in the evening, and with the second wife in the morning. Venturing on suitable inquiries, I learned from the husband that my surmise was correct, the habits of the two women probably not varying these respective times of congress.

"One swallow does not make a summer;" nor do marital peculiarities in one family establish a physiological rule. The above, which may be numbered as Case I., is but a single instance in a series that has come under my observation. A few from the list may be mentioned briefly.

CASE II.—H——, owner of a bakery, arose between 2 and 2.30 A.M., leaving his wife asleep; usually lay down soon after his evening meal and took a nap, and retired with his wife about 9.30 P.M. They had six boys and no girl. He informed me that he probably never had had connection except in the evening hour, soon after retiring.

CASE III.—C—— was a merchant, fond of going to his club about 9 P.M., and returning about midnight. The wife usually retired about 10.30, rarely knew when the husband came to bed, and the two rose quite late in the morning. Five girls were born, but no boy. Then his business and place of residence changed, he was beyond reach of his club, and then usually retired with his wife about 10.30. After this change in life, three boys were born, but no girl. He told me his habits led to marital indulgence in the morning during the years when the girls were born, and in the evening when the boys were born; and he thought these times of cohabitation had not varied during those respective periods.

CASE IV.—K—— had three sons and three daughters, born in interrupted order as to their sex. He told me his wife announced her consciousness of each conception within half an hour after the fruitful intercourse, from sensations that to her were satisfactory; and she had kept a record of them all, partly from curiosity and partly as data in preparing for confinement. He kindly obtained from her, and gave to me, a copy of this record. It showed the conception of the three boys as having occurred respectively at 10, 10.30, and 10.30 P.M.; and of the three girls at respectively 5.30, 5.30, and 6 A.M.

CASE V.—Mrs. R——, a widow at the time I made inquiry, was mother of three boys and one girl. She told me she knew positively that the three boys, born consecutively, were conceived in the evening; and that the one girl was conceived in the morning. Delicacy forbade questioning as to details.

CASE VI.—Mrs. M——, an extremely punctilious lady, was mother of a daughter, two sons, another daughter, another son. She said she knew, in the most unquestionable manner, the moment of each of these five conceptions; and that the conception of the two daughters occurred in the later morning hours before rising, and those of the three sons in the evening hours soon after retiring. The husband said she announced to him, in peculiarly emphatic terms, the fact of each conception within a few minutes after its occurrence.

These six cases are typical of seventeen others within my knowledge, all equally clear. To give the other seventeen in detail would be merely cumulative. In yet fifteen other families, the general data bear out the same thought, but are not equally definite. They years ago gave me the belief that male children are conceived in the evening, before the midnight hour; and that females are conceived in the morning hours. To help confirm this belief are the following: In thirty-five years of professional life, I have attended in a number of cases where children were born out of wedlock. In nineteen (19) of these cases the mothers gave me full information as to the hour of fruitful connection. Sixteen of these nineteen children were boys. Thirteen of these boys were conceived between the hours of 10 and 11.30 P.M.; two were conceived between 4 and 5 P.M.; and the other about 7 P.M. Three of the nineteen were girls, and these were conceived, respectively, about the hours of 2 A.M., 4.30 A.M., 6 A.M.

A few opportunities have arisen for testing the correctness of my view, and thus far they seem to sustain it. Mr. C. E.'s lady had three girls in succession, and he consulted me as to the possibility of perpetuating the family name through a boy. I advised adherence to evening congress, strictly. He said his habit had been chiefly, though not invariably, in the morning; and possibly this accounted for three girls. My suggestion was followed rigidly for five years, during which time two boys were born to him; after that he did not adhere to the evening hour, and a girl was born. In two other instances I gave the same advice; it was followed, and boys were born. In one instance the morning hour was advised and followed, and a girl was born. In other instances my advice was not adhered to with sufficient exactness to be of value, though apparently sustaining my view.

I offer no theory in the matter, for the data are not sufficient. In the above cases, and in a much larger number of others, it would seem that the wife has altogether the least responsive feelings in the morning, and most in the evening. This may not be at all uniform with wives; and even if it were uniform, it may not influence the sex of the child. I merely offer the few facts I have gathered, presenting only those which are clear and determinate. Perhaps they will not correspond with information gathered by other gentlemen, although they coincide with facts imparted to me by a few professional friends, to whom I have mentioned my views within the last twelve years. It would be interesting to know if the profession at large has any clear data on this line of thought; and whether the sum of such informa-

tion sustains, throws into doubt, or quite overthrows my idea that boys are conceived before midnight, and girls in the morning hours.

WM. H. COOK, M.D.

CINCINNATI, O.

THE CURE OF HICCOUGH BY SNEEZING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It may be gratifying to Dr. Robert B. Wilson to learn that his treatment of singultus is classical, and was recommended by Hippocrates, as the aphorism given below will show. The following appeared in the April, 1886, number of the *New York Medical Abstract*, and was credited to Dr. G. A Gibson in the *Edinburgh Medical Journal* of the same month: "No doubt many of my professional brethren are acquainted with the Hippocratic aphorism 'Υπὸ λυγμοῦ ἐγγενομένου πταρμὸς ἐπιγενόμενος λύσει τὸν λυγμόν,' 'Sneezing occurring after hiccough removes the hiccough,' or, as it is rendered by Adams, 'Sneezing coming on in the case of a person affected with hiccup, removes the hiccup.'" When devoting a leisure hour to Plato's Dialogues, as translated by Jowett, I was struck by a passage in the Symposium, which had never arrested my attention before. Translated by Jowett, it stands thus: "When Pausanius came to a pause, Aristodemus said that the turn of Aristophanes was next, but that either he had eaten too much, or, from some other cause, he had the hiccough, and was obliged to change with Eryximachus, the physician, who was reclining on the couch below him. 'Eryximachus,' said he, 'you ought either to stop my hiccough, or to speak in my turn until I am better.' 'I will do both,' said Eryximachus; 'I will speak in your turn, and do you speak in mine; and while I am speaking, let me recommend you to hold your breath, and if this fails, then to gargle with a little water; and if the hiccough still continues, tickle your nose with something and sneeze, and if you sneeze once or twice, even the most violent hiccough is sure to go. In the meantime I will take your turn, and you shall take mine.' 'I will do as you prescribe,' said Aristophanes, 'and now get on.'" The hiccough was not cured by the first nor by the second remedy suggested by Eryximachus, but by the production of sneezing. The method of tickling the nostrils has been tested by us in cases of obstinate hiccough, and has been very successful. It is not necessary that the stimulus applied to the nose be followed by sneezing; the application of a gentle irritant to the nasal mucous membrane may be quite enough to put a stop to the hiccough, by diverting the nervous energy into other channels, although it may not be of sufficient power to induce sneezing.

Yours truly,

J. BENNETT, M.D.

SCRANTON, PA., June 7, 1886.

LAPAROTOMY IN ABDOMINAL WOUNDS.

TO THE EDITOR OF THE MEDICAL RECORD.

MY attention has just been directed to an article, "Laparotomy in Abdominal Wounds," in your issue of May 8th. It is astonishing how "chaotic" is the notion of many Europeans relative to America and her works, but in reality, the notion of some few in the East, relative to the West, is not remarkably less "chaotic." In answer to *The Lancet*, THE MEDICAL RECORD, in an editorial, is satisfied by simply stating: "It is very well known to American surgeons that it was the cases of Dr. W. T. Bull, and subsequently those of Dr. J. B. Hamilton and others, which specially turned attention in this country to laparotomy for abdominal wounds." The case of Dr. Bull was published in the month of February, 1885; that of Dr. J. B. Hamilton, in September, 1885. Previous to this, however, in the spring of 1884, at the meeting of the American Medical Association at Washington, Professor C. T. Parkes, of Chicago, read a paper, presented diagrams—living and anatomical specimens of the result of an extensive series of experiments on dogs. These experiments were made with the avowed purpose of ascertaining what should be done in gunshot wounds of the intestines. The animals were shot, the abdomen opened, the wounded parts of the intestines treated with appropriate surgical methods, and the external wound closed—in fact just such treatment adopted as, the necessary changes being made, would suggest itself to any surgeon now when confronted with an abdominal wound associated with indications of a perforation of the viscera. It would seem as though, in correcting the statements of a European journal, that an American journal would take some cognizance of the labors of the men in the western part of America. The article detailing the particulars of these experiments of Professor Parkes, was published in full both in the *Medical News*, and in the *Journal of the American Medical Association*. I mail you a copy of the reprint. We do not think THE MEDICAL RECORD means to discriminate between the East and West, and that it will accord this short notice in the cause of accuracy. To show that some did not fail to see the bearing of Professor Parkes' observations on abdominal surgery, we venture a short extract from a lecture by Professor W. W. Keen, of Philadelphia, and published in the *Popular Science Monthly* for May, 1885. "In May of last year, Parkes, of Chicago, reported to the American Association a series of systematic experiments on thirty-seven dogs, that were etherized, then shot, the abdomen opened, and the wounds of the intestines, arteries, mesentery, etc., treated by appropriate surgical methods. The result confirmed the belief awakened by earlier experiments and observations, that surgery could grapple successfully with multiple and formidable wounds, by sewing them up in various ways, or even by removing a piece of the bowel and uniting the cut ends. Hard upon the heels of this important paper, and largely as its result, comes a striking improvement in practice. . . . November 2d of last year, a man was brought to Chambers Street Hospital, in New York, with a pistol-shot wound of the abdomen. Under careful antiseptic precautions, and following the indications of Parkes, the abdomen was opened by Dr. Bull."

ROBERT TILLEY.

JAMAICA, L. I., June 7, 1886.

QUININE IN TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: We do not intend "to beard the lion in his den," nor anything especially audacious, in entering this mild but decided protest against the too sweeping remarks of Dr. George M. Dewey, as quoted and largely indorsed by your journal in its issue of May 22, 1886.

The closing remarks of the editor in reference to the routine use of quinine and other antipyretics in continued fevers are timely enough; but taking the article as a whole, the inevitable bearing it has is to drive a large number of readers entirely from the use of that drug in the treatment of typhoid fever.

Such a scare was not needed in a large scope of Georgia territory, where every fall the "busy practitioner" meets more or less of this tedious malady.

Within the last decade—certainly embracing the period during which quinine and other antipyretics have been used directly with the view of combating dangerous temperature—we have not known an instance wherein we were assured that it was being used prejudicially to recovery in typhoid fever.

There are many instances of it, doubtless, for the world is abundantly sprinkled with routine and extremist doctors. To the latter class, in all sincerity, we would certainly relegate any medical man who could to day write—"The Utter Worthlessness of Sulphate of Quinine in Typhoid Fever."

Thirty years' experience in watching the behavior of the fever in question, with little medicine, with no medicine, and with quinine, and plenty of it, overwhelmingly convinces us of its very great value in the treatment of typhoid.

With all that has been written on it, from Hutchinson to his critic Dewey, the profession is largely at sea about the treatment.

Within the last ten years we have often had occasion to observe the unsettled and indefinite views of many members of the medical profession as to its pathology and clinical history. Not a few have failed to discover that a man ordinarily has the disease but once in life.

One and another has scarcely discerned that his too vigorous cathartic, with which he opened the case, has produced complications ever afterward beyond his control; that the patient who passes the night without morphine and without rest will inevitably report worse the next day; and now, seemingly, we would infer from Dr. Dewey, of Maine, that a protracted high temperature means only tissue waste, and finds its proper antidote in "sweet milk." Hutchinson deserved the rebuke given by his less distinguished reviewer, but for not advising quinine in larger doses. During the many years we have been giving it in large doses in typhoid fever and with the most gratifying results, we have not found *any* good in the use of it in "three- or four-grain doses four times a day." Nor do we use it at all until the temperature passes 102°, and shows a plain tendency to go higher. But when the exacerbations, daily, in general, mount up to 103° or 104°, to the manifest distress of the patient and the production of visceral congestions, fraught with structural changes of a vital nature, to say nothing of the tissue waste inseparable from such a "fast life," we give a capsule containing eight to ten grains of quinine every four hours, beginning early in the morning and repeating till three are taken—then discontinuing until the following morning, and so on, with more or less variation, suited to difference in constitution and environment, until the temperature stands again at a figure compatible with the patient's comfort and safety. The happiest results have followed, and no one is more cognizant of the source of relief than the taker himself, who, as such, is apt to be in pretty good possession of his faculties. A temperature that may be followed for many days without serious injury to the organism in one case, will jeopardize life in the next.

E. P——, a robust farmer, aged thirty-five, confined to the bed for one week—seen for the first time—remarks: "My fevers have been very high and made me feel bad; I don't think I have any now, and am feeling better." A corrected thermometer, placed under his tongue three and a half minutes, reveals a temperature of 104°.

Mrs. M——, a lymphatic lady, with small, soft pulse, aged fifty, has been under observation ten days. Has typhoid fever, temperature not exceeding 102° in the exacerbation. Second week, temperature averages a little higher daily, until it reaches 103⅘°, during the acme of the exacerbation, and she is in extremities, and every symptom threatening.

An eight-grain capsule of quinine, given every four hours till the temperature is 102° in the hot stage, makes her not only comfortable, but removes every symptom of impending visceral complication.

Of course we recognize and take it for granted, in the discussion of this question, that it is conceded by all, that the essence of the disease is intestinal eruption, splenic congestions or engorgements, and internal hyperæmia everywhere; and in speaking of visceral complications we mean to refer to the exaggerated and disorganizing degrees of these lesions. Time and again, self-accused, we have thought perchance we were drifting into that professional Slough of Despond that knows no excelsior cry, viz., routineism, and have put the stopper in our Powers & Weightman and let it remain there day after day and visit after visit; and have as often been reminded to return to it, and in doing so have realized that fortunate state of being in happy accord with our client.

A mere record of recoveries may be a very narrow view of medical progress, but, as a test of good therapeutics, strikes with some force both in the profession and the laity. To jump theories and circumlocution and call for results is truly American. Measured by this rough and ready rule, an experience of the last ten years, with constantly enlarging opportunities for exhibiting the drug in sporadic and endemic features of the disease, pronounces strongly in favor of sulphate of quinine as a remedy of inestimable value in the treatment of that form of continued fever generally known as typhoid.

As to the nosology of typho-malarial fever we are in perfect agreement with the article referred to in the issue of May 22d. The malarial "tail" has no practical bearing, only as it serves to delude some shallow thinker into modifying his plan of treatment. For whoever treats his so-called typho-malarial case differently, or with an eye less singly directed to the main life-imperilling lesions, because of this doubtful appendage "malarial," will, except he is rescued by the kind offices of that great conservator—the natural tendency to recovery—meet with eminent defeat.

In the treatment of typhoid fever, as in every disease of possible gravity, we try to approach the bedside with no preconceived ideas as to diagnosis or treatment. On each separate visit we would let the clinical facts alone account for the day's medication, keeping steadily in view Thomas Watson's great injunction, "*the tendency to death.*"

Proceeding thus, we have found it abundantly profitable to give veratrum and aconite, and always associated with an opiate, mostly morphine, to procure rest and calm an excited circulation; cold alkaline baths and frequent changes of linen, preferably administered (the bath) during the exacerbation, for general hygiene; "sweet milk" with or without whiskey for feed, and *quinine* in emphatic doses whenever the temperature produces notable discomfort or threatens to produce dangerous complications in the run of the fever. Barring the accidents of profuse hemorrhage, or intestinal perforation, recovery has been the rule.

HARRIS FISHER, M.D.

EASTMAN, GA., May 25, 1886.

ANÆSTHETICS IN CHILD-BIRTH, FROM A RELIGIOUS POINT OF VIEW.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: A prominent physician of this city lately requested me to express my opinion as to whether there were any religious objections to the application of anæsthetics during delivery. The reason for this request was, that ladies in travail often refused to be placed under the influence of chloroform, on the ground that such practice was against the words of the Bible: "In sorrow (pains) thou shalt bring forth children."

As other physicians, probably, sometimes meet with similar objections on that ground, I beg leave to say a few words on this subject.

It is true that the words just referred to are found in the Book of Genesis, ch. iii., verse 16, as having been addressed by the Lord to mother *Eve*. But these words must by no means be taken literally as a divine *command* to every woman, so as to make it a duty for her to suffer the pains and pangs of parturition without being permitted to apply means to alleviate them, or to become insensible to them. In the same passage of Scripture, in which these words are addressed to the first woman, as a penalty imposed on her because of disobedience, we also read the words directed to the first man: "In the sweat of thy face shalt thou eat bread." Now, if we are to take the former words literally as a divine injunction to every

woman, we must do the same with the latter words addressed to man, so as to make it sinful for everyone to eat bread, except in the sweat of his face. But no religious man ever scrupled to dry the sweat of his brow before eating his bread, or to eat a morsel before his face was bathed in perspiration.

The Jewish religion never attached to the narrative of the so-called *Fall of Man* that importance which Christian theology attached to it by basing thereon the doctrine of Redemption. Rational interpreters of Scripture in the Middle Ages already were inclined to divest that narrative of its literal sense, and regard it as a sublime allegorical legend intended to illustrate sin's origin, its progress, and its evil consequences. In accordance with the general view of Holy Writ, that moral causes are underlying all events and occurrences of human life, man's usual toils and troubles in gaining his sustenance, and woman's cares and sorrows connected with her maternity, are here represented as consequences of disobedience against the divine will. If we look upon that narrative in this light, the words "In sorrow shalt thou bring forth children" are as little a divine commandment as the words "In the sweat of thy face shalt thou eat bread," but both sentences are rather a description of what usually happens to woman and to man. In this light even the ancient Rabbis viewed that passage. For, while pointing out all commandatory and prohibitory laws of the whole Pentateuch, to the number of 613, they wisely refrained from counting the words just referred to among those laws.

Although the use of anæsthetic agents (soporific potions) under surgical operations was not unknown in antiquity, and is occasionally even mentioned in the Talmud (B. Metzia, fol. 83[b], where it is termed *Samma d'shina*, somnific drug), still the practice of applying such agents to women in travail is of too recent an origin to have been considered by the ancient Rabbis. Had they known it, they would certainly not have objected to it, as they expressly provided that the criminal, before an execution, should receive a narcotic potion, which the noble women in Jerusalem used to prepare for him in order to be rendered insensible to the sufferings of a capital punishment (Talmud Sanhedrin, fol. 43[a]). If he who was to suffer death to atone an atrocious crime was permitted to be rendered insensible to his deserved suffering, what wrong can it be for our good and tender ladies to be placed under influences that remove from them the pains and pangs of maternity?

M. Mielziner, M.D.,
Professor in the Hebrew Union College.
Cincinnati, O., June 1, 1886.

The Drug Business in Kansas.—A student in the Michigan University recently applied to the proprietors of a drug store in a Kansas town for a position as prescription clerk. In reply he received the subjoined letter, which is printed just as it was written, except that the names of the town and of the firm are suppressed. It throws some light on the operations of the prohibitory liquor law in that State: "Dear Sir yours Recd in Reply i will Give you a Brief Description of our Business Perhaps you understand the nature of a Drug Store in knansas we Do Some liquor Business in a Back Room By the Drink our Prescription trade Runs from two to three thousand Pr year Some Clerks objects to the Back Room trade I Give you the facts in the case So that you will not be Disappointed your Board By the week will cost you from $3.50 to $5.00 a week now if you accept this Position answer By telegraph at once as I kneed a clerk very bad & must have one as Soon as Possiable. Yours truly"

For Excessive Perspiration of the Hands, washing with a saturated solution of boracic acid is often effective.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from [illegible], 1886.

McParlin, Thomas A., Colonel and Surgeon. Granted leave of absence for two months, with permission to apply for an extension of one month. S. O. 146, A. G. O., June 25, 1886.

Page, Charles, Lieutenant Colonel and Surgeon. Leave of absence extended ten days. S. O. 146, A. G. O., June 25, 1886.

Magruder, D. L., Lieutenant-Colonel and Surgeon. Granted leave of absence for two months, to take effect on or about July 1, 1886. S. O. 146, A. G. O., June 25, 1886.

Vickery, Richard S., Major and Surgeon. Assigned to duty as Surgeon in Charge of Army and Navy General Hospital at Hot Springs, Ark. S. O. 150, A. G. O., June 30, 1886.

PROMOTION.

Brown, Joseph B., Lieutenant Colonel and Surgeon. To be Surgeon with the rank of Colonel. January 24, 1886.

Heger, Anthony, Major and Surgeon. To be Surgeon with the rank of Lieutenant Colonel. January 24, 1886. Circular, A. G. O., June 28, 1886.

Official List of Changes in the Medical Corps of the United States Navy during the week ending July 3, 1886.

Green, E. H., Passed Assistant Surgeon. Ordered to Naval Laboratory at Brooklyn, temporary duty.

Brown, J. M., Medical Director. Member of Retiring and Examining Board.

Ogden, F. N., Assistant Surgeon. Ordered to Juniata.

Siegfried, C. A., Surgeon. Three months leave abroad.

Hall, J. H. H., Passed Assistant Surgeon. Detached from Museum of Hygiene, ordered to Naval Hospital at Brooklyn.

Wentworth, A. R., Assistant Surgeon. Detached from St. Louis and ordered to the Brooklyn.

Corbin, J. Decker, Assistant Surgeon. Ordered to St. Louis.

Berryhill, T. O., Assistant Surgeon. Ordered to Museum of Hygiene.

Neurasthenia and Abdominal Belts.—The inhabitants of this globe, says *The Lancet*, may suffer from nervous weakness, or neurasthenia, simply because they neglect to wear abdominal supports. At least that is the conclusion that naturally follows from the recent teaching of M. Glénard, of Lyons, who believes that some cases of nervous exhaustion are attributable to gastroptosis, or lowering of the stomach; to hepatoptosis, or descent of the liver; or to nephroptosis, which is another name for floating kidney. Imagine the following colloquy in a physician's consulting room: Patient: "And now, doctor, after all this sounding and examination, pray tell what is the matter with me." Physician: "My dear sir, you have habitually bolted your meals, which have likewise been too abundant; as a consequence you have caused your stomach to descend from its natural situation—*facilis descensus Averni*—and this gastroptosis, as we call it, has acted seriously on your nervous system, hence your languor, irritability, and general loss of tone, etc. My advice to you is to read 'Stuapmore,' put on an abdominal belt, and cultivate a waist!"

Medical Items.

COCAINE is of no value in sea-sickness.

PHTHISIS AND THE NEGRO.—According to Dr. F. Tipton, of Selma, Ala., before the war, the negro never had phthisis, now it is the greatest scourge among them.

THE NEGRO FROM A MEDICAL STANDPOINT.—The negro is rarely or never myopic. Their only eye trouble is phlyctenular conjunctivitis. They rarely have granular lids. The negro bears surgery remarkably well. Syphilis in the negro is generally very mild. One half of all negro men have syphilis, and it does not seem to seriously hurt them. Gonorrhœa is easily cured in the male. In the female it does most harm, causing endometritis and sterility. The negresses often have uterine fibroids, but very rarely ovarian tumors. Uterine cancers are very rare, although lacerations of the cervix are very common. Insanity is rare.—DR. TIPTON in *N. Y. Medical Journal.*

THE ANCIENT PRIESTS AND THE MICROCOCCUS PRODIGIOSUS.—In using the potato as a growth-medium for micro-organisms, Koch imitates the priests who in old times scratched some religious symbol with a needle-point upon a potato, and presented it to people, who were astonished some days after to find the symbol in blood-like letters on the surface of the potato. The priests made use of a fungus known as the prodigiosus, whose chief characteristic is a purple, blood-like growth. Cut open a potato and, with a needle dipped in the fungi, trace a line upon the newly-cut surface; some days later the line will appear in dark purple. Koch uses the potato for various growths.

THE MICROBES IN MILK AND WATER.—It has been calculated that in a cubic centimetre of milk—about twenty drops—there may be between 2,000,000 and 3,000,000 microbes, and possibly hundreds or thousands of different kinds; and the next twenty drops of milk may contain as many more varieties. The microbes in a drop of water taken from the well may consist in a number of straight rods; at the end of an hour these rods break in two, and in another hour another division takes place, the number doubling about every hour. Every minute that the water is exposed to the air adds to its hundreds of microbes, and yet water is pronounced good or bad, according to what the analyst sees through his microscope or thinks he sees when the water finally reaches him in his laboratory.

POST-DECAPITATION PHENOMENA.—Professor Martin (*Centrb. f. d. Med. Wiss.*, Nos. 40 and 44, 1885) relates that he once was present with Professor Rossbach at a decapitation where the division occurred between the fourth and fifth cervical vertebra. The trunk dropped down lifeless and with every muscle relaxed, simply obeying the law of gravity, while the head continued for one and a half minute to make dyspnœa-like respiratory motions, just like a person who, when suffering from the most intense dyspnœa, would endeavor to breathe.

BRUISES.—Dr. S. M. French recommends an ointment of equal parts of extract of belladonna and glycerine for the relief of the pain following a bruise.

STERILITY AND OBESITY.—Dr. A. Brondel writes in the *Bulletin Général de Thérapeutique* that he was consulted by a married lady on account of sterility, which caused her great unhappiness. The lady was excessively corpulent, so much so that the nurse was obliged to lift up the fat on the mons veneris with both hands before a speculum could be introduced. The genital organs were healthy. The patient was placed on a spare diet in order to reduce her obesity, and persevered in the regimen ordered for eighteen months, at the end of which time she had lost forty-four pounds in weight. The menses, which had formerly been irregular, returned, and the patient soon after became pregnant.

CHEWING GUM AS A FATTENING AGENT.—A Southern secular paper is authority for the following statement regarding the fattening effect of chewing-gum: "Twenty years ago the rule was the Southern women were thin and delicate; it is not the rule now. Southern women are not physically equalled in all North America. Any physician who is as well informed as he ought to be, will tell you that this is true. This change is due to the habit of chewing gum. You may smile, you may even laugh if you please, but I am telling you a plain fact. As to Southern men, they are as thin and gaunt as they ever were, and so they will remain until they cease to chew tobacco and begin to chew gum."—*Medical and Surgical Reporter.*

REPORT OF THE MISSION HOSPITALS AT SWATOW AND UNG-KANG-FU.—We have received the reports of these hospitals for the year 1885. The institutions are under the care of Drs. P. B. Cousland and J. F. McPhun. At Swatow 5,637 patients were received, 3,867 of whom were in-patients. There were 944 operations performed. At the hospital in Ung-Kang-Fu, under the care of Dr. Riddel, there were 2,620 patients treated, of whom 400 were in-patients; 180 operations were performed, including 23 teeth extractions. Instruction was given to a class of native junior assistants and pupils in materia medica and therapeutics during the fall and winter, the students being taught the Latin names of the drugs. The religious work of the hospitals is reported to have been moderately successful.

SCIENTIFIC ARDOR OR OBSTINACY?—Some of the female medical students in Boston would seem to require instruction in ladylike deportment as much as in medicine. The *Boston Medical and Surgical Journal* says that there have been some scenes in the operating-room of the City Hospital, during the last few weeks, which were not calculated to inspire the beholder with chivalric sentiments toward the female sex, as represented among the students of one of the medical schools of the city. In defiance of the distinct rules of the trustees regarding admission to the operation, certain women have repeatedly forced themselves into the seats, even during the performance of private operations upon the private parts of private male patients, so that the operator was obliged to remove his patient to another room. This course was continued even pending action by the trustees of the hospital on demands of the petitioners.

POISONOUS FISH.—In an article on "Poisonous Fish, and Fish-poisoning in China," in the *Chinese Recorder* for February, 1886, Dr. D. J. Macgowan says, that the flesh of the porpoise is regarded as one of the greatest delicacies, but that it is apt to be exceedingly poisonous, many persons dying every year from eating it. All cases of fatal poisoning, however, appear to be due to neglect of certain precautions that should be observed, as the rejection of certain portions of the fish, and long boiling of the part that is to be eaten. The symptoms are those of paralysis of the extremities and tympanites.

THE USE OF COCAINE IN GYNECOLOGY.

BY GEORGE WOODRUFF JOHNSTON, A.M., M.D.,

[illegible]

MANY new drugs and preparations have been introduced to the world of late years. Announced by their discoverers or manufacturers in the most boastful and pretentious terms, they have enjoyed a transient notoriety and then have speedily been forgotten. Cocaine, however, offers a most remarkable exception to this rule. Vaunted by the public press and by the members of different branches of the medical profession as peculiarly suitable to the treatment of each of a variety of pathological conditions, differing widely as to nature and location, in spite of its popularity it has lived, and enjoys to-day a degree of confidence rarely meted out to any single pharmaceutical preparation. That this confidence is justly deserved no one can doubt who has had any extended experience with the drug. Indeed it may be said with truth, we believe, that no such valuable addition has been made to our pharmacopœia since the discovery of ether, of which, curiously enough, it has become a dangerous rival. In view of all this it is much the more to be regretted that the isolation of so valuable an anæsthetic as cocaine cannot be clearly and without question attributed to one individual. The weight of opinion, however, seems to be in favor of Niemann as the one "who first (1859) gave to cocaine a certain amount of physiological individuality," although the claims of Percy and Gardeke are not without an appearance of truth and justice. Be this as it may, its value as a local anæsthetic was, after a considerable interval of time, systematically tested by Koller (1884) in the eye, and Jelinek (1884) in the throat, with results in both cases most eminently satisfactory. To Fränkel, of Breslau, perhaps, more than any other, is due the credit of first (1884) calling the attention of gynecologists to its value, and recommending its use in the treatment of many of the diseased conditions found in women. Since then its efficacy has been tested in a variety of conditions calling for the production of limited surface insensibility. So far as we are aware, aside from reports of its effects in a few individual conditions, and broad generalizations as to the limit of its value in the diseases of women, American gynecological literature is barren of information in regard to cocaine. It has not been the fortune of the author to meet anywhere with an account of a systematic series of experiments in regard to the range of its adaptability, and many points which could be settled only by collective investigation remain unsettled. It is the object of this paper to present a brief outline of as much as possible of what has been written in relation to the employment of cocaine in gynecology, and to add the histories of a very few and widely dissimilar cases in which is to be read nearly the sum total of the author's own experience with the drug in the diseases of women. Such a contribution will, the author believes, not furnish, but aid to a slight degree, some others in furnishing the results of a complete, accurate, and satisfactory study of cocaine in its relations to gynecology, so that this drug, whose value has not been even yet generally or fully appreciated, may reach thereby the full measure of its usefulness.

There are many purposes in gynecology for which anæsthesia is employed. It is often impossible to make a complete and satisfactory vaginal examination, for the nervous system is always very irritable in affections of the genital system without its aid, and there are but few operations which can be performed unless preliminary surface insensibility, and hence, some degree of general muscular relaxation, have been secured. Under the term reflex cramp of the muscles of the pelvic floor,[1] a variety of conditions have been described which serve to render adequate diagnosis, or the employment of local treatment, painful, difficult, or impossible. Mere reflex cramps, originating in mental or physical excitation of a local era of hyperæsthesia, situated at some point at or near the urethral, vaginal, or rectal outlet, in women who are anæmic and neurasthenic, manifest themselves as painful spasms of one, a group, or of all the muscles of the pelvic floor. The forced contracture of those ring muscles or sphincters which serve, when in a state of health, to maintain a proper degree of tonicity in the walls and at the outlets of the three pelvic floor-clefts, accentuates the prevailing degree of tonicity or markedly exaggerates it, until closure of these canals, more or less absolute, supervenes. Irritation of the local areas of hyperæsthesia and contraction of the muscles of the pelvic diaphragm are accompanied by pain, amounting in some cases to the extremest agony, which is entirely out of proportion to the nature or degree of either the irritation or of the muscular spasm. The most gentle attempts at separation of the labia, or introduction of the examining finger, will often call forth greater pain and more marked muscular contraction than the roughest manipulation. To properly appreciate the especial cause of these reflex cramps, and often to institute appropriate methods of treatment, anæsthesia is necessary. To meet these indications ether, in this country at least, has been generally employed, and to secure a few moments' insensibility to pain and muscle relaxation, it has been necessary to submit patients to the inconveniences of etherization.

If we are to rely on the testimony of reported cases, however, its use is no longer necessary. Its place has been largely taken by cocaine. By the aid of the latter drug, without the slightest constitutional disturbance, we are enabled, it is said, to thoroughly overcome any local hyperæsthesia or sphincteric contraction there may be, thus rendering accurate and complete diagnosis possible, while suitable therapeutic procedures may be at once successfully and painlessly instituted.

It is stated that in cocaine we have a cure for vaginismus. Reflex painful cramp of the sphincter vaginæ (constrictor cunni) muscle, when proving a cause of dyspa-

[illegible] Read at meeting of the Washington Obstetrical and Gyne[illegible] June 28, 1886.

NOTE.—For an account of the early history of the employment of cocaine [illegible] many points of interest connected with it, see Koller, Wien. Med. W[illegible] 1884, No. 45, p. 44; Jelinek, Wien. Med. Wochenschr., 1884, No. [illegible]; THE MEDICAL RECORD, New York, 1884, xxv., 5; Editorial in [illegible] Report, New York, 1884, xxvi., 521; Archibald, Geo., Knapp, [illegible] in Ophthalmia and General Surgery (New York and London, 1885); Hergott, [illegible] l'Emploi de la Cocaine dans la Pratique Medicale et Chirurgicale [illegible] also, Revue Med. de l'Est, Nancy, 1884, xvi., 177, 225; Wien. Med. [illegible] trali, Wien, 1884, xxv., 1, 2; also, Prag. Med. Wochenschr., 1884, [illegible] 466; Fränkel, Ueber Cocain, als Mittel zur Anästhesirung bei Operationen [illegible] (Centralbl. f. Gynäk., Leipzig, 1884, viii. 777-780); Corning, Local Anæsthesia in General Medicine and Surgery, etc., New York, 1885.

reunia, may be done away with by the use of cocaine in solution, oleate, or suppository; but unless the cramp is due to a condition likely to be removed by forced sexual congress, the employment of cocaine will prove of but temporary service. For in some, if not the majority of these cases, the lesion producing the reflex cramp will be aggravated by sexual intercourse, even though sensation in the parts be dulled, and after the temporary effect of the drug has passed away it will be discovered that connection is just as painful or impossible as before. It was found, in the interesting cases narrated years ago by Sims, that "ethereal cohabitation" was worse than useless; and, although the anæsthesia of cocaine may also permit of complete and satisfactory sexual congress, it will no more cure the disease than will intercourse with the patient under the influence of ether. It is therefore only in certain conditions, as, for example, when an unyielding hymen or a too narrow vaginal orifice offer a mechanical barrier to defloration, that its employment is at all justifiable. For it is very well known that cocaine can have little or no direct local effect in the cure or removal of those pathological conditions located about the vaginal outlet which give rise to reflex spasm; that these lesions are made worse, not better, by forced manipulation or intercourse, even under a local or general anæsthetic; that the much sought after pregnancy ending in labor aggravates and does not benefit them, but that rest is the absolute preliminary to their proper treatment. And, further, in many cases this vaginismus may be not the symptomatic expression of disease located at the vulva or vaginal outlet, the area covered on the application of the drug, but of a lesion, relatively speaking, far removed from the seat of spasm, and totally unaffected by the local anæsthetic. From what has been said, therefore, it may be concluded that in cocaine we have an invaluable aid in the induction of transient local anæsthesia, for the purpose, in suitable cases, of making difficult and painful vaginal examination satisfactory and painless; but that the plan of employing cocaine indiscriminately in the great variety of conditions grouped carelessly under the term vaginismus, although perhaps temporarily successful in relieving the symptoms of pain and spasm, and permitting the introduction into the vagina of the examining finger, specula, or the male sexual organ, is productive of no permanent good, and too often indirectly induces an aggravation of the very disease which it is sought to relieve.

The following abstracts of cases exhibit examples of the employment of cocaine in reflex cramp of the muscles of the pelvic floor. The word "cure" may often be freely translated "temporary relief."

Svot ("Chronic Vaginismus treated by a five per cent. Solution of Muriate of Cocaine and Vaseline," *Russ. Med.*, St. Petersburg, 1885, i., 460–462). Dyspareunia. Mind filled with terror at every thought of connection. Treated without benefit for ten years. Extreme sensitiveness of vaginal walls. Application of cocaine and vaseline. Successful and painless coitus. Pregnancy three months later. Svot thinks patients should be encouraged to think they will get well; this is an important element in treatment.

Dujardin-Beaumetz ("Sur un cas de Vaginisme traité avec succès par le chlorhydrate de cocaine," *Bull. gén. de thérap.*, etc., Paris, 1884, cvii., 489). Patient not nervous or hysterical. Intercourse first became painful, and then impossible, after birth of first child, and so continued for two years. Labor difficult; no forceps, no perineal rupture. Vaginal examination painful, difficult; chloroform, forced dilatation of orifice of vagina; no relief. Gradual dilatation with speculum; no relief. Painted internal face of lesser lips and whole circumference of vaginal orifice with a two per cent. solution of cocaine. Disappearance of local sensitiveness in one minute. Painless introduction of speculum. Application repeated four times. Cure. Has obtained equally successful results in other cases not enumerated.

Fränkel (loc. cit.). Young woman, married six weeks. Mucous membrane of introitus hyperæmic, swollen, injured in several places. Great sensitiveness and reflex cramp on attempting to introduce examining finger. Painted thrice, at two-minute intervals, with a twenty per cent. solution of cocaine. Repeated easy and painless introduction of finger.

Butaud ("Des applications thérap. de la cocaïne en gynécologie," *Rev. méd-chir. cl. mal. d. Femmes*, Paris, 1885, vii., 201–220; see, also, reprint from above, Clermont, 1885. Daix, 8vo). Patient with vulvo-vaginitis. Violent pain on introduction of finger; cannot introduce speculum. At least touch, spasm of sphincter vaginæ and transverse perineal muscles. Sexual intercourse long impossible. Pain on sitting down suddenly or riding. Application of a ten per cent. solution of cocaine for five to six minutes to hyperæsthetic region. In two minutes partial, and in five minutes complete, absence of pain or spasm on introduction of examining finger or speculum. Sensibility returned in ten minutes. Application repeated on six following days. Less violent contraction of vulvar ring on irritation of zone of hyperæsthesia. "Mais la cocaine n'ayant qu'une action temporaire sur le vaginisme." In this case there was "ulceration of the neck."

The same. Young woman; very nervous and susceptible; married two years. Never had been able to have sexual intercourse. Vaginal examination impossible. Application of a ten per cent. solution of cocaine for three minutes in hymeneo-vulvar furrow. Examination easy, introduction of speculum painless, nervousness diminished. Dilatation. After twenty-six applications intercourse possible. In this case there was spasm of transverse perineal muscle.

The same. Patient married four years. Sexual intercourse very painful, but not impossible. A ten per cent. solution of cocaine applied. Temporary relief only. Reapplication; excision of irritable carunculæ myrtiformes, seat of pain. Sensibility of parts returned in a quarter of an hour. Cure complete. In this case there was spasm of transverse perineal and constrictor vaginal muscles.

Thomas, C. H. ("Some Uses of Cocaine in Gynecology," *Med. News*, Philadelphia, 1885, lxvii., 567; also, *Maryland M. J.*, Baltimore, 1885–86, xiv., 80–82, Case of "Hyperæsthesia of Vagina with Mild Vaginismus"). One-grain cocaine suppository put in vagina half an hour before each treatment. Abolished spasm. Introduction of speculum easy and painless. Thomas used cocaine successfully in a case of vaginismus in which an examination was impossible.

Schrank ("Vaginismus and its Treatment with Cocaine," *Wien. Med. Wochensch.*, 1885, xxxv., 1140–1143, 1181–1184; also, transl. in *Louisville Med. News*, 1885, xx., 321–337). Patient believes vaginismus is due to irritation of a local lesion, which consists in a rupture of the hymen extending into vaginal tissue, produced at first by coitus and aggravated by contact. Pain and spasmodic phenomena. Recommends the use of a stronger solution of cocaine. With a four per cent. solution anæsthesia often delayed twenty minutes; requires frequent pencillings. After cocainization of the parts, gradual dilatation with Weiss' anal speculum; no pain. Cure complete, when the vagina is so large that no abrasion of the seat of hymeneo-vaginal laceration occurs on coitus. In two cases observed, immediately after period, more frequent application or stronger solutions were necessary to get anæsthesia of introitus.

Cazin ("Vaginisme datant de six ans, disparation du Spasme Vulvaire, rapprochements faciles par les Cacligeonnages et l'injection intravaginale d'une Solution de Cocaïne à deux pour cent," *Bull. et Mém. Soc. de Chir. de Par.*, 1884, N. S., x., 949). Patient a young woman, married six years. Sexual intercourse has always been impossible. Least touch on external genitals causes violent pain—even convulsions. A slight erosion at the

fourchette the cause of trouble. Advised forced dilatation under chloroform; not permitted. Later, patient advised to apply a two per cent. solution of cocaine to external genitals, and also to inject the same into the vagina through a catheter. Tried four days after period. Attempt at intercourse, five minutes later, absolutely without pain. Cocainization repeated before each coitus. Result only temporary. Pregnancy. Cazin believes that spasm and hyperæsthesia disappear after first labor.

Droiahl ("Behandlung des Vaginismus," *Centralbl. für Gynäk.*, Leipzig, 1886, x., 99; also, *Journ. of Nervous Diseases*, 1885, No. 10). Patient with vaginismus, treated with vaginal injections and applications to external genitals of solutions of chloral and borax (borax, 15.0; hydrate of chloral, 3.0, and distilled water, 250.0). "Bromhydrate, 0.006, and camphor bromat., 0.06," three times daily by the mouth, with iron. After eight days painless cohabitation. Early conception.

Droiahl quotes from the *Moniteur thérapeutique*" the history of a case of vaginismus. Pencilling of the external genitalia and vaginal injections of two per cent. cocaine solution made painless coitus possible in a few minutes.

Willmott ("Cocaine in Vaginismus," *Austral. Med. Jour.*, 1885, No. 10; also, *Centralbl. für Gynäk.*, Leipzig, 1886, x., 318). Young woman, married ten weeks. Coitus could not be accomplished, each attempt produced severest pain. Forced dilatation of constrictor; removal of hymen; improvement. Three fingers introduced into vagina without pain. After four weeks the original sufferings returned. Pencilling with four per cent. solution of cocaine half an hour before coitus made it painless. General condition of patient improved. She conceived soon after.

Von Ramdohr (*New York Med. Jour.*, 1884, xl., 588). Von Ramdohr succeeded in making an examination in a case of vaginismus, which had resisted every previous attempt, by brushing the mucous membrane with solution of cocaine.

Hoffmann ("Ueber die Anwendung des Cocains in der frauenärztlichen Praxis," etc., *Wien. Med. Presse*, 1884, xxv., 1594–1596, u. 1623–1627). Case 1: Patient young, handsome, and intelligent; general health good; muscles affected by reflex cramp—sphincter vaginæ, anal muscle, muscles of thigh, especially adductors, and the muscles of the abdomen. Contraction as if by faradic current, a veritable "muskelspiel." Introitus vaginæ inflamed and covered with muco-purulent discharge; this area, even if gently touched with cotton, is the seat of pain and origin of reflex cramp. Intense redness, blanched, and examination made possible and painless by the introduction into the vaginal inlet and vagina of suppositories of thirty-five milligrammes of cocaine. Piece of charpie soaked in a three per cent. solution of cocaine laid in the vagina and changed every two to three hours. Before each subsequent examination cocaine suppositories put in rectum. Marriage possible within one month.

Case 2: Patient married twenty months. Fourteen days after wedding husband complained that intercourse had been impossible. Thin muco-purulent discharge from vagina and meatus (husband had contracted gonorrhœa one year before), hymen ruptured, caruncule swollen, whole introitus inflamed. Severe pain on slightest touch; examination impossible. At end of one month's treatment could not introduce index-finger into vagina. Patient went to another physician. Returned to Hoffmann no better—local condition same as before. Cocaine suppositories, 0.035, per anum, and charpie pledget soaked in a three per cent. solution of cocaine laid in vaginal inlet. Vagina irrigated with astringent and disinfectant solutions, painted vaginal mucous membrane with a solution of cocaine, and introduced a cotton tampon soaked in solution of cocaine. Repeated next day. Coitus without pain or obstacle; first since marriage, twenty months before. Vagina cocainized three times in ten days.

The author. Patient a young girl, nervous, thin, anæmic, married two years, came to woman's clinic, Central Dispensary, for treatment.

History: Intercourse always difficult and painful; more since birth of only child, one year ago. At each attempt agonizing pain at vulva, and spasm of sphincter vaginæ. Impossible to introduce pipe of syringe, on account of pain and spasm. Intercourse entirely discontinued. Pain on walking and sitting.

Examination: On attempt to separate labia violent reflex cramp. Impossible to introduce examining finger. Pencilling of cleansed and dried accessible parts of introitus with a twenty per cent. solution of cocaine. Interval of five minutes. Attempt to introduce finger failed. Renewed application of cocaine; interval six minutes. Thoroughly successful digital exploration of vagina made without spasm and with but little pain. Pledgets of cotton, soaked in cocaine solution introduced into vagina and allowed to remain throughout examination.

Vagina malposed, lumen narrowed one-half by pubic arch crossing it midway;[1] uterus enlarged and retroverted; cervix lacerated. Attempt at introduction of speculum failed. In mid-line at post-commissure an elliptical, deep, angry-looking fissure, and a few areas of superficial erosion. Touch, though slightly painful, borne everywhere but here. Spasm reproduced, though not so violently as before, on touching fissure with camel's-hair brush. Primary cause of cramp, narrowing of vagina; immediate cause, fissure produced by attempts at intercourse, and aggravated by subsequent attempts, and by difficult and instrumental labor.

Subsequent history of case: In spite of prolonged and industrious use of cocaine, fissure showed no signs of healing, nor spasm and pain of ceasing until local rest and appropriate surgical treatment directed to the fissure had been instituted.

In this instance the temporary effect of cocaine was excellent, but total failure to secure any permanent relief after a fair trial of drug alone.

The chief interest in regard to the employment of cocaine in gynecology concerns its use in operative work. The question whether operations about the vagina and cervix are possible, without general ether or chloroform narcosis, has been settled in the affirmative. A considerable number of these operations have been done successfully without any anæsthesia at all, either general or local, but this practice, except in rare and unusual cases, is inadmissible. We have, therefore, at hand two anæsthetics, a general and a local, ether and cocaine, and we are often called upon to decide between them.

It is true, at the outset, that the employment of ether is rarely accompanied or followed by serious results; but in the search for the causes of mortality in operations, even of an apparently trivial nature, ether must always be considered as a possible, though not a probable cause; and when it can be done, all such possible causes of increased death-rate should be eliminated. But further than this, the amount of constitutional disturbance, even if it be but simple annoyance, often induced by ether, when most judiciously administered, and after careful preparation of the patient for narcosis, is entirely out of proportion to the gravity or duration of the operation. Indeed, for a few moments, complete loss of sensibility and of muscular rigidity, a patient is often subjected to hours of subsequent suffering and prostration.

It should be remembered by those most accustomed to giving ether indiscriminately in general, private, or hospital practice, that the gynecologist is called upon to

[1] This condition was [illegible] which the vagina was [illegible] Washington Obstetrical and Gynecological Society, by Dr. George Byrd H[illegible]. The author of this paper, at the same meeting, mentioned a further [illegible] the deformity, in which the vestibule was excoriated and [illegible] the male organ.

treat a class of cases—women, sensitive, bloodless, broken-down with suffering—who, however well they may yield to the influence of the anæsthetic, suffer markedly from its effects, and recall the incident with horror. In the eyes of a busy surgeon the etherization of a patient is not an affair of any great moment and is soon forgotten. But in the eyes of the patient the whole thing is different; it is an event in her life; it is dreaded as much in anticipation as the operation for which it is the preliminary, and frequently causes more after-suffering. It is a thing to be avoided. The very thought of it frightens patients into declining necessary surgical interference, which would be willingly sought if etherization was unnecessary.

It may be said, we believe, that cocaine is preferable to ether in a large number of gynecological operations. Its use is equally to be recommended in securing the briefest possible local anæsthesia, or in maintaining areas of tissue in a state of complete insensibility during the course of the most protracted operation, and it is especially indicated when the condition of the heart or kidney negatives decidedly the employment of ether or chloroform. By a series of the most remarkable operations, Emmet has been able to construct a urethra again and again, when apparently no tissue was to be found anywhere for this purpose. It has been necessary to give ether for each operation of this and of a similar kind, but cocaine would probably answer the purpose just as well, and all danger from the too frequent use of ether would thus be obviated.

When properly used, cocaine procures what is wished—local insensitiveness of tissue—and nothing more, and there is no drug whose external application is freer from difficulty or danger.[1]

There is no area in the body in which, after operative interference, union by first intention is more desirable than the female genital tract. In many operations union by granulation and cicatrization is synonymous with failure, and cicatrices exhibit in women the most extraordinary propensity—not so extraordinary as some would have us believe, however—to become the sources of reflex irritation and of pain. Everything should be done by properly cutting, cleansing, and approximating the wound edges to obtain rapid and permanent healing. But after-rest for a part is no less necessary than cleanliness and proper coaptation. Absolute rest, or any thing approaching it, is impossible in the case of the uterus, vagina, bladder, urethra, or rectum. In respiration the tissues comprising the pelvic diaphragm, and those adjacent to, and in relation with it, move as do the thoracico-abdominal septum and the contents of these two cavities. But these movements are slow and gentle, nor are advance and regression great; the tissues are never stretched. This cannot be said when the pelvic diaphragm is violently agitated by efforts at emesis following etherization. Anyone who has watched the rapid and forced movements of the anterior vaginal wall, for example, when the perineum of a vomiting patient is retracted by a Sims speculum, may be justly fearful of the success of an operation on tissues so stretched and tumultuously agitated. And it is in those operations, where absolute union of freshened edges is requisite, as in the relief of vesico-vaginal fistula, and where, to secure this union, rest, as near complete as possible, is necessary during the first twenty-four or forty-eight hours after the operation, that the employment of cocaine is most singularly applicable. That some patients do not vomit under or after ether, does not invalidate the truth of the foregoing statements, nor does the fact that many surgeons secure the most happy results under the most adverse circumstances. The efforts made in administering ether by the rectum, to do away with the effects of its inhalation in the usual manner, were successful in so far as the "gagging" and vomiting were concerned. But aside from the great dangers of rectal etherization, such a plan is unsuitable in operations on the female genitalia, except in securing primary, or as a preliminary to complete anæsthesia, when the vapor is to be subsequently inhaled.

The range of the usefulness of cocaine is, however, restricted. It can at best procure but a limited anæsthesia. It is essentially non-diffusible; chilling the sensibility only of the surfaces with which it comes in immediate contact, or the tissues in nearest anatomical relation with them. When an operation has to be performed requiring extensive superficial anæsthesia, this anæsthesia is easily produced. But in deep operations it is a question as to just how valuable cocaine is. By repeated applications of the drug, by deep hypodermatic injections, and by the use of strong solutions, the difficulty may be partly overcome. But in the graver operations which the gynecologist is called upon to perform, no reliance can be placed on cocaine, and the chances are they will ever remain beyond the pale of its usefulness, which, with few exceptions, will be confined to the vagina and portio vaginalis.

For one reason alone its employment in some of the simpler and nearly all the graver operations will be inapplicable, and the use of ether will continue to be preferred. However great a degree of anæsthesia of the tissues to be operated upon is induced, the patient will be constantly aware that something is being done, and there will be a tendency on her part, involuntary perhaps, to shrink away from the edge of the table and the reach of the operator. This will require readjustment of the speculum, if one is being used, and the operation will be constantly delayed while the patient is placed in a more satisfactory posture. But more important still, cocaine does not procure that complete absence of all muscular rigidity as does ether narcosis, which is of advantage in all gynecological operations, and absolutely necessary in some. At the most critical point of an operation, when it is necessary to secure a bleeding vessel, or obtain absolute coaptation of two denuded surfaces, the patient, exhausted by the constrained position in which she lies, begins to move about. In the experience of the author there has been more suffering during and after the operation from the maintenance for a long time of one position, and that not a natural or particularly easy one, than from the direct present or after affects of the operation itself. His patients have become restless, and have complained of tired and aching limbs. A comfortable operating-table can always be provided, but it is not always that an operation requiring no little nicety and precision can be done quickly, except by the most practised. When the patient is of an extremely nervous disposition, these difficulties become exaggerated, and ether is a necessity.

One cause of pain and discomfort—prolonged and forcible traction with the Sims speculum—can be eliminated by painting with cocaine, and rendering insensitive the surfaces by the tissues so drawn and compressed (Polk).

If the effect of cocaine on the healing of wounds, in tissues permeated by it, has not been investigated, it would seem that some data on this subject should be collected from experiments on man or the lower animals. If such investigations have been made, the author regrets that an account of them has not come to his notice. No conclusive dicta can be laid down as to the use of cocaine in gynecology until this has been determined. Cocaine must produce a marked degree of contraction of peripheral vessels, for tissues become blanched under its application, and in the author's own cases and others reported elsewhere, there has certainly been less hemorrhage during operations than is customary. How long this local anæmia lasts, whether long enough to exert any

[1] Whether ... [illegible] ... is [illegible] ... constitutional effect ... [illegible] ... solution were thrown under the skin of the back in two or three places to prepare the way for the use of [illegible] ... [illegible] ... were [illegible] ... [illegible]

effect upon rapid union or not, are both questions which he would not attempt to answer. In all the reported cases in which cocaine has been used, the rapidity and success of union has either been stated to have been satisfactory or else has received no comment. In no case in gynecological practice, so far as he has been able to ascertain, has any unfavorable influence on the healing of wounds been noted. In each of his own cases union has been all that could be desired.[1]

This faculty possessed by cocaine of diminishing the calibre of blood-vessels, and hence of the amount of blood in a part, has been taken advantage of in the treatment of inflammations of the vaginal mucous membrane. In the milder kinds of vaginitis it forms alone an available application, and in strong solutions is highly recommended as a preliminary or accompaniment to the use of nitrate of silver, sublimate solutions, etc., in the more severe types of gonorrhœal inflammation.[2]

Cocaine has been employed in solutions of various degrees of concentration in gynecology. Of these the four per cent. seems to represent the lowest effective strength, the ten per cent. the medium, and the twenty per cent. solution the highest that has been employed.[3] The degree of both local and general sensitiveness decides the necessary strength of the solution. As a rule the four per cent. solution acts sufficiently well to produce a decided and somewhat lasting effect when the conditions as regards general and local insensitiveness, superficiality of tissues to be affected, etc., are favorable. When these conditions are unfavorable; when the patient is nervous and susceptible; when the field of operation is hyperæsthetic, extensive, or removed from the surface; when the operation is likely to be a protracted one, the stronger solutions are found to be the most satisfactory. Injections with the hypodermatic syringe into the submucous tissues, or repeated pencilling with weak solutions, are quite effective; but the first is often unnecessary, and the second tedious and unsatisfactory.[4] The tendency among gynecologists, particularly in Germany, is toward the use of strong (twenty per cent.) solutions of the muriate, and unless it is some day shown that the action of the drug in this concentrated form is prejudicial to wound-healing, the use of the more powerful solutions, as being at once simple, rapid, and effective, will become general.[5]

The sensation of stinging, heat, or burning, imparted to tissues by the use of the twenty per cent. solution has never been noticed by the author.[1]

But as there are various lengths of time over which an operation may extend, and as there are various degrees of local and general sensitiveness, no unconditional assertion can be made as to the strength of the cocaine solution to be employed.

The methods of using cocaine in gynecology are given in sufficient detail in the histories of the appended cases. For external application, to render the absorptive capabilities of the part as great as possible, the field of operation must be thoroughly cleansed, preferably with soap and water, and then carefully dried. If carbolic or sublimate solutions are used, it should be before the application of the cocaine, and the parts dried as before. Continuous irrigation of cocainized surfaces during operations is difficult to carry out with success.[2] It is well, after first thoroughly pencilling the part with a solution of the desired strength, to apply a thin layer of absorbent cotton soaked in the same fluid over the surface, and allow it to remain for a certain interval.[3] This is simpler than frequent pencillings. The length of time required for thoroughly anæsthetizing a part depends of course on the strength of the solution, the rapidity of absorption, and other variable factors. Although the effect of the drug is sometimes very rapid, the tendency among operators is rather to wait too short than too long time, especially if it be not taken in minutes.[4] The loss of sensation in some accessible areas can be roughly determined by touching the parts with a pin or pointed instrument, at first gently and then with some force. From the observation of the author, with a twenty per cent. solution, although in a very few moments the parts are well anæsthetized, the maximum effect is reached in about four to six minutes. With a weaker solution a little longer time is required.

In some situations the deep submucous injection of weak solutions answers an excellent purpose, while in positions where tissues are thick and the absorptive power is not good, rubbing the drug, in the form of solution or ointment, well into the previously cleansed and dried surface will insure the requisite degree of anæsthesia.[5] The effects of cocaine last a variable length of time.[6] During an operation it is extremely difficult to repeat its application, but with care and patience the bleeding surfaces may be sufficiently dried to make the action of the drug possible, or submucous injections may be repeated. Where operations are performed involving an extensive surface, by commencing the denudation at the lowest possible point, so that surfaces above may be always dry, and uniting wound edges from below upward, areas to be denuded and united may be cocainized step by step as the operator comes to them. This, however, is not always possible.

It is well known that cocaine acts most effectively in tissues which have been rendered anæmic,[7] but it is difficult to drive the blood out of the parts upon which the gynecologist operates. The author has endeavored to reach this end, but with what success he is unable to state, by the administration of a prolonged and very hot vaginal douche just before applying the drug. By means of a neat little instrument devised by Bache Emmet, of

[1] Bosworth, see Knapp, loc. cit. Applied to [illegible] cocaine to nasal mucous membrane. In twenty to thirty seconds contraction of venous sinuses under mucous membrane. Entire depletion of part in three minutes[!]: later, anæsthesia; capillaries and blood-vessels affected in like manner. Mode of action—causes by absolute contact contraction of unstriped muscle-fibres. Does not act through nerve-supply. Time required for cocaine to act, proportionate to absorptive power of mucous membrane; more rapid in columnar than squamous epithelium; more rapid in children than in adults. Contraction of venous sinuses persists about twelve hours, or over. Dr. Canon Morgan, of this city, stated, in conversation with the author, that from a series of (unpublished) experiments in operations on the throat, he was convinced that cocaine delayed union and increased the risk of subsequent hemorrhage. Howe: New York Medical Journal, August 8, 1885. Series of experiments on healing of same lesions of both eyes in the same animal, cocaine being used in but one. Conclusions: Imperfect solutions do not appear to hinder the healing process in lesions of iris, conjunctiva, or cornea. As strong solutions possess strong antiseptic properties they would seem to exert a favorable effect in this respect. The above quoted by Corning, loc. cit., who says: "What influence cocaine has on the healing of wounds is a question that can be answered inductively, and that the above observations go far toward furnishing a definite conclusion. In each of the author's cases of trachelorrhaphy, extensive oozing after operation, coming on after an interval of twelve to twenty-four hours. In each case the period came on prematurely, which is, however, not unusual, and was excessive."

[2] Fränkel, Butaud, Thomas, loc. cit.

[3] Fränkel in his early experiments, which were made [illegible] and sensitive tissues, used two to five per cent. solutions [illegible] without decided results. A piece of cotton soaked in a two to five per cent. solution was laid in the vagina and allowed to remain five, ten, or fifteen minutes [illegible] subsequent reduction of sensibility. He next used a ten per cent. solution, but has finally come to rely upon a twenty per cent. solution almost exclusively. He recommends the following formula: ℞. Cocain. muriat., 1.0; aq. destil., 3.0; spir. vini rect., 2.0. To keep up effectiveness of solution a few drops of alcohol must be added from time to time. [Aqueous solutions of the muriate are, the author believes, generally used in this country.]

[4] Schramm (Cocain als lokales Anästheticum bei Prolaps Operationen, Centralbl. für Gynäkol., Leipzig, 1885, ix. 225–227) says his next experiments will be to ascertain if cocaine cannot be rendered more effective by applying it externally, or in subcutaneous or submucous injections in combination with morphia and other narcotics.

[5] Butaud, quoting Koenigstens, says, that in ophthalmic operations the anæsthetic power of cocaine increases from two per cent. to ten per cent., and diminishes beyond this degree of concentration. He believes that in gynecology the ten per cent. solution is sufficiently strong for the usual run of cases, and that the twenty per cent. solution should be reserved for use in active inflammations, as vulvitis and gonorrhœal vaginitis. [It is possible that in gynecology there may be some highest efficient strength of cocaine solutions yet undetermined, and that above this point solutions will increase instead of subduing tissue sensitiveness. A great deal of the variability in the action of different solutions of the same nominal strength is said to be due to some kind of deterioration. Boracic acid gr. ij. to cocaine solution 3j. will insure sterility and prevent one kind of deterioration. For some time the author supposed that aqueous solutions of the muriate of cocaine lost their strength with age, and had fresh preparations made before each attempt at cocainization. Of late he has used with perfect success solutions that have been made for months, and have remained in bottles carelessly corked since they were prepared. He does not know what has been the experience of others in this regard.]

[1] Schramm: loc. cit. Fränkel: loc. cit. [2] Schramm, loc. cit.

[3] Engelman: Weekly Medical Review, Chicago, 1885, xi., Suppl., 10, 17, 25. Engelman more than any one else insists on the desirability of this method of practice.

[4] Butaud, loc. cit. In some subjects fifteen minutes are required for complete absorption. Thomas, loc. cit., says, [illegible]

[5] Butaud, loc. cit., says powders have not been tried in gynecology, but, according to Jelinek, in the throat have [illegible] of solutions.

[6] Butaud, loc. cit., says we cannot [illegible] of absolute insensibility.

[7] Corning, loc. cit.

New York,[1] the tissues of the urethro-vaginal septum can be made bloodless preparatory to the "button-hole" operation, and the use of the uterine tourniquet might be revived to produce the same effect before trachelorrhaphy.

By surface pencilling with strong solutions it is believed that in nearly all the simpler and more frequent plastic operations about the vagina and cervix a sufficiently deep and prolonged anæsthesia may be produced.

In the removal of silver sutures, especially from the perineum, sometimes a very painful procedure, cocaine has been recommended and is much employed.[2]

After the preceding generalizations it may not be inappropriate to take up in detail the gynecological operations and procedures in which cocaine has been recommended or employed. Strange as it may seem, the published material to draw upon in accomplishing this result is scant, and represents, in the belief of the author, but a very small part.

Of the experiments made, or experience gained in the use of cocaine, an outline of the histories of individual cases is given, often in the words of the reporter, and observations of gentlemen whose names are not unknown in gynecology.

Some procedures are described which, it is thought, are not in accordance with the views of many American gynecologists.

I. The Vulva, Perineum, and Vagina.—1. *Retention of menstrual blood due to atresia of some part of uterogenital canal. Butaud* (*loc. cit.*) advises its use in operations for the above condition. He says that ether is inadvisable in many cases, for vomiting may cause rupture of the sac containing blood.

2. *Laceration of the perineum, true and so called; prolapse of the vaginal walls and of the uterus, cystocele, urethrocele, etc.* For use in operations upon the perineum and anterior and posterior vaginal walls, perineorrhaphy, and anterior and posterior colporrhaphy, cocaine has been suggested and has been tried with success.

Thomas (loc. cit..) says that Levis, of Philadelphia, has used cocaine with success in such plastic operations in the vagina.

Polk, of New York, recommends in perineorrhaphy the injection of four to five minims of a four per cent. solution of cocaine into the sides of the vagina, just within the ostium, and thoroughly rubbing the solution into the field of operation and its neighborhood.

The author can find no notice of the use of cocaine in primary operations on the perineum.

Schramm (loc. cit.). Case 1: Anterior and posterior colporrhaphy. Nervous subject. Prolapse of anterior and posterior vaginal walls; descensus uteri to the scissura vulvæ; no perineal tear. Sublimate douche; parts dried. Field of operation pencilled with a twenty per cent. solution of cocaine until pale and bloodless. Areas to be denuded and united; previously cocainized *seriatim*. In posterior colporrhaphy cocaine was applied five times with silver wire. Duration of entire operation two and a quarter hours. Only very seldom did patient give signs of there being sensation in parts. No rise of temperature. Union by first intention throughout.

Case 2: Anterior colporrhaphy and colpo-perineorrhaphy. Weak and anæmic. Prolapse of anterior and posterior vaginal walls; descensus uteri to lower third of vagina; retroflexion; laceration of perineum. Technique of cocaine application same as above, twenty per cent. Silver wire and buried catgut sutures. Duration of operation, two and a half hours. No pain. Subsequent progress uncomplicated and without fever. First intention.

In the above operation seven grains, or twenty per cent. cocaine solution was used. In part these operations are done by assistants.

Schramm says anterior colporrhaphy can be done without general narcosis, but not posterior colporrhaphy, for it is very painful.

Bataud (loc. cit.). Case 1: Laceration of perineum, involving sphincter ani. A ten per cent. solution of cocaine applied and well rubbed into parts (massage) for six to seven minutes. Each separate area to be denuded and united was thus treated when reached by the operator. Sensibility was diminished, but anæsthesia was not complete, for pain (slight) was felt on introduction of sutures. Anæsthesia persisted for twenty minutes. If flow of blood was diminished, it was to a very slight degree.

Case 2: Laceration of perineum up to sphincter ani.; prolapse. Ten per cent. solution of cocaine. Sulphuric acid applied to two surfaces of a gutter, in order to obtain union between them. No pain. Sensation had not returned at end of eighteen minutes.[1]

The author. Anterior colporrhaphy; Emmet's anterior wall operation. Woman's Clinic of Central Dispensary and Emergency Hospital, April 21, 1886. Negro woman; lymphatic disposition. Cystocele, urethrocele, uterine prolapse. Field of operation cleansed, and six injections of a four per cent. solution of cocaine, in all twelve to fifteen minims, thrown under the mucous membrane of the anterior wall. Very slight bleeding and no pain during the operation. One silver suture to secure three points at front and sides of cervix. Elliptical and crescentic denudations united with a continuous catgut suture. Perfect union.

Drs. Harrison, Fry, and W. W. Johnston, members of this Society, were present at the operation, as was Dr. Magruder, a member of the attending staff of the hospital.

3. *Cyst of the vagina. Schramm* (loc. cit.) recommends the use of cocaine in excision of vaginal cysts.

The author. Operation on cyst of anterior vaginal wall. Woman's Clinic of Central Dispensary and Emergency Hospital, June 12, 1886. The patient upon whom this operation was performed presented herself for treatment in April last.

Two vaginal cysts, situated on the anterior wall, were discovered. The fluid was partly withdrawn from them by means of a hypodermatic syringe, was examined, and an outline of the case reported to this Society. The patient at the time declined further operation. She returned on June 10th, having suffered much pain since her last visit. On account of her dense ignorance it was difficult to tell the nature of her sufferings. She was, she said, incapacitated for work. The cysts were found distended with fluid. The vaginal aspect of the larger cyst was cleansed, dried, and pencilled with a four per cent. solution of cocaine. Pledgets of cotton soaked in the same solution were kept in contact with it for six minutes. No douche given. A piece of the wall was then excised, the cavity of the cyst evacuated, and stuffed with iodoform gauze. There was some little pain during this operation, and disturbance after it, but the patient declined to stay in the hospital and went home.

As was feared, the opening showed a tendency to close; therefore, on June 12th nearly all of that portion of the cyst-wall projecting above the vaginal level was removed with a scissors, after the parts had been subjected to the influence of a twenty per cent. solution of cocaine, on pledget of cotton, for six minutes, and the membrane lining the cyst-cavity stitched to vaginal mucous membrane with ten catgut sutures, as recommended, we believe, by Schröder. There was considerable hemorrhage during this slight operation. There was no pain during or after it. Dr. Fernald, a member of this Society, was present.

4. *Vesico vaginal fistulæ. Schramm* (loc. cit.) recommends the use of cocaine in operations for the relief of vesico-vaginal fistulæ.

Doughty uses muriate of cocaine in operative gyneco-

[illegible] sequent discussion by Coe, Mundé, and Emmet.

[2] Polk, Knapp, loc. cit.

[1] I [illegible] to understand [illegible] case, or the [illegible] sulphuric acid in order to unite a rupture of the perineum.

logy and vesico-vaginal fistula (The Medical Record, New York, 1884, xxvi., 658).

Case of vesico-vaginal fistula. Very small fistula. Knee breast posture. Thorough cleansing of [illegible] surface. Two applications (two drops each) of two per cent. solution of cocaine made three minutes apart. Two minutes later fresh application; repeated in five minutes. In three minutes anæsthesia complete. Denudation for period of sixteen minutes, then for first time pain. Solution reapplied. Denudation completed in thirteen minutes, without pain. Patient put in Sims' position to rest. On resuming operation introduced first two sutures; considerable pain. Reapplication of solution. Introduction of remaining four sutures without pain. Very slight bleeding, noticed flow of blood increased as effects of the cocaine wore off. Coagula seemed firmer than usual.

Polk (Knapp, loc. cit.). Case of vesico-vaginal fistula. Small fistula. Four minims of four per cent. solution of cocaine injected on each side of fistula one-half inch away. Mucous membrane of bladder and vagina around fistula freely painted. Operation; no pain or discomfort.

5. *Pruritis vulvæ.* *Engelmann* (*St. Louis Courier Med.*, 1885, xiii., 248–254) says cocaine relieves itching of pruritis vulvæ.

Hoffmann (loc. cit.) employed cocaine with marked success in three cases of pruritis vulvæ. It was used in the form of an ointment, with vaseline, in the proportion of 3 to 100, and applied as often as the itching became annoying.

6. Cocaine has been employed very successfully as a preliminary step in the cauterization of the soft chancre.

Polk (Knapp, loc. cit.), four per cent. solution of cocaine.

Thomas (loc. cit.).

Butnam (loc. cit.), observations at the Lourcine, Paris, with five per cent. solution of cocaine.

II. The Uterus.—1. *Curetting.* *Schramm* (loc. cit.): Patient irritable and nervous; objected to chloroform narcosis. Rapid dilatation of cervical canal with Hegar's instruments of hard rubber; uterine cavity washed out with sublimate solution; dried with cotton wrapped on sound. Cotton impregnated with cocaine solution introduced on sound into cavity; allowed to remain five minutes. Thorough and satisfactory curetting and injection of undiluted liq. ferri sesquichlor. No pain; slight discomfort only. Further progress uncomplicated.

Fränkel (loc. cit.). Case: Curetting, slight pain. Fränkel advises above-described plan of treatment, but allows cocaine solution to remain in contact with walls of cavity for fifteen minutes, using pledgets of cotton impregnated with the drug.

Engelmann (*Medical Review*, loc. cit.) narrates interesting instances of the intra-uterine use of cocaine occurring in his own practice.

2. *Dilatation of the cervical canal; section of the cervix; use of actual cautery for removal of commencing epithelioma; curetting canal; ignipuncture; scarification of cervix, etc.* *Polk* (Knapp, loc. cit.) remarks that sensitiveness of cervix being less marked than that of most of genital tract, it is the more readily influenced by cocaine; that incision and forcible dilatation of the cervix, the use of caustics and of the sharp curette, the use of the actual cautery (in cases of commencing epithelioma), have all been practised satisfactorily and painlessly by the employment of cocaine. He recommends the injection of three to five minims of a four per cent. solution of cocaine into regions that are to be cut, stretched, or scraped.

Engelmann (*Medical Review*, loc. cit.) suggests the use of cocaine before rapid dilatation of the cervical canal, and the use of sponge-tents.

Case: Firm contraction of external os in a cartilaginous cervix. Painless dilatation of os and cervical canal two minutes after application of a four per cent. solution of cocaine on cotton.

Butaud (loc. cit.). Case 1: Very nervous woman. Ignipuncture of cervix. Forty punctures in forty-five minutes; six applications of cocaine; no pain. Sensibility returned in twenty minutes after operation.

Case 2: Very nervous woman. No pain. Ignipuncture, Butaud says, consists in introduction of the heated point of galvano cautery into tissues of cervix thirty, forty, fifty, or one hundred times, to the depth of fifteen to twenty millimetres. (See, by the same author, "De l'ignipuncture profonde du col de l'uterus," *Rev. Méd.-Clin. des mal. d. Femmes*, Paris, 1886, viii., 10–24.) This procedure is made painless by the application of a ten per cent. solution of cocaine to the neck, and repeated every ten minutes until the end of the operation. Sometimes, in spite of cocaine, the heated points are felt. Advises the use of cocaine before *scarification* of the neck.

Schramm (loc. cit.) recommends cocaine in *Schröder's operation for excision of cervical mucous membrane and in galvano-caustic amputation of portio vaginalis.*

Chéron (*Rev. Méd.-Clin. d. mal. d. Femmes*, Paris, 1884, vi., 664) has employed cocaine in two cases of ignipuncture which were rendered entirely painless by means of four successive applications of a five per cent. solution of cocaine.

Fränkel (loc. cit.). Experiments. Two deep punctures of cervix (according to Spiegelberg) loudly complained of. Surface then twice pencilled with a twenty per cent. solution of cocaine, and for five minutes cotton soaked in a solution of the same strength left in contact with eroded portio. Punctures; no pain.

3. *Trachelorrhaphy; Emmet's operation for laceration of the cervix uteri.* *Polk* ("Hydrochlorate of Cocaine as a Local Anæsthetic in Gynecology," The Medical Record, New York, 1884, xxvi., 489). Case 1: Double laceration of cervix uteri extending on both sides to cervico-vaginal junction. Parts washed with warm water and soap; dried. Cervix: Its canal and adjacent vaginal wall painted with a four per cent. solution of cocaine three times, at two to three minute intervals; after last, three minutes' wait. Operation elaborate of its kind; cicatricial plug from each angle. Time of operation, forty minutes. No pain or discomfort. In last ten minutes some soreness.

Case 2: Patient has less self-control than above. Preliminaries same as before. Acute pain; after twenty minutes application (fourth) was made. After three minutes' wait the operation was continued, and completed without pain. Polk says cocaine retarded blood-flow in first case.

Roeth ("Cocaine in Trachelorrhaphy," *American Practitioner and News*, Louisville, 1886, N. S., i., 37; see, also, *Boston Medical and Surgical Journal*, 1885, lxii., 527). Case 1: Laceration of cervix to vaginal vault on right side, admitting finger into cavity of uterus. Three hypodermatic injections into cervix, one on each side of rent, and one at base of sulcus. Five minutes' wait. Painted surfaces to be denuded. Shortly after began operation. No pain throughout. Quantity of drug used ℥ ss+. Roeth says in future he will use cocaine in preference to ether.

Fisher ("Trachelorrhaphy with Cocaine," *Northwest Lancet*, St. Paul, 1884–5, iv., 440). Case 1: Lateral laceration of cervix extending quite to vaginal junction. Tried general anæsthesia; abandoned on account of bad behavior of the heart. Operation postponed two days. Cervix brushed lightly with a four per cent. solution of cocaine; five minims injected into either lip about four lines from ulcerated surface. About thirty minims used in all. Usual operation: no pain or inconvenience, except from constrained position of patient and traction on the uterus. Union good. Fisher says cocaine is a good substitute for anæsthesia, but it does not secure relaxation of muscular tissues nor permit of uterus being drawn as near the vaginal orifice as is otherwise possible.

The author. Three cases of trachelorrhaphy. Case 1: Patient of lymphatic temperament. Bilateral lacera-

tion of cervix down to vaginal junction; tissues hypertrophied, rolled out, cystic, eroded, cicatricial. Hot carbolized douche; parts dried. Cervix, cervical canal, and vaginal fornix painted once with a twenty per cent. solution of cocaine. Six minutes' wait. Operation (May 27, 1886) very extensive. Hemorrhage very slight; absolutely no pain; silver wire. Time of operation, from first application of cocaine to twisting of last suture (a hot antiseptic douche being given before coaptation of parts), one hour and ten minutes. After operation no rise of temperature, no pain or discomfort. Discharge of blood from vagina began twenty-four hours after operation, and lasted twenty-four hours. Premature menstrual period five days after operation; more profuse than usual; lasted usual time. Sutures removed on fifteenth day, one at left angle on eighteenth day; union perfect. Dr. Fry, who is present this evening, will bear witness to the painlessness of this operation.

Case 2: Patient a very nervous and excitable woman, almost hysterical at beginning of operation. Slight right-sided tear of cervix, and considerable cicatricial deposit at angle. Operation June 12, 1886. Field of operation cleansed, dried, and pencilled as before. After first pencilling, a pledget of cotton, soaked in a twenty per cent. solution of cocaine, left in contact with cervix for six minutes. Time of operation estimated as before, forty-five minutes. When half over, cocaine applied very unsatisfactorily to denuded edges. Hemorrhage inconsiderable, less than what might have been expected; silver wire. Patient restless and fearful during operation, afterward assured author there was no pain attending it.

Drs. Fry, Fernald, and W. W. Johnston assisted the author in this operation.

There was slight oozing of blood from the vagina for twenty-four hours after the operation; no pain, subsequent discomfort, or fever.

Case 3: A very nervous patient. An extensive bilateral tear, up to internal os and outward to vaginal junction. Lips thin; tissues everywhere soft; no effort at nearing a deposit of scar tissue. Considerable erosion. Operated May 29th. Preparation of field of operation as in Cases 1 and 2, twenty per cent. solution of cocaine being used. The internal edges of the already made flaps freshened and brought together; very little hemorrhage; silver wire and two catgut crown sutures. Patient very restless, but suffered no pain during or after operation. Time estimated as before, one hour and ten minutes. No rise of temperature. Considerable oozing began twelve hours after operation; lasted one day. Period came on prematurely and was more profuse than usual. Drs. Fry, Cutts, and Johnston were present at this operation. Sutures removed on eighteenth day. Union perfect.

Of these three cases, operated upon by the author, all were white, one only being a hospital patient. One cause of pain and suffering during and after trachelorrhaphy was avoided by keeping the uterus fixed with tenacula, but exerting no irregular or injudicious traction upon it.

Schramm (loc. cit.) recommends the use of cocaine in Emmet's operation (trachelorrhaphy).

Engelmann (*Medical Review*, loc. cit.) describes a case of trachelorrhaphy done by Mundé, of New York. Solution of cocaine injected into cervix. No pain until introduction of deep sutures. Author has not seen original reference.

Fränkel (loc. cit.) describes a case in which cocaine was used successfully in forcibly breaking up some post-uterine inflammatory adhesions, thus restoring the uterus to its proper position.

III. URETHRA.—1. *Dilatation of urethra.* [illegible] ("Cocainum Hydrochloricum als Anästheticum bei der Simian'schen Dilatation der weiblichen Urethra," *Centralblatt für Gynäkologie*, Leipzig, 1885, ix., 695). Patient very anæmic, nervous, and susceptible. Diagnosis made of tumor in the bladder; to complete diagnosis dilatation of urethra was desired; chloroform contra-indicated by condition of heart, etc.; bladder emptied by catheter; cotton wrapped on sound and soaked in twenty per cent. solution of cocaine put in urethra, and application of same strength of solution to vaginal wall and about meatus; four such applications of cocaine solution in twenty minutes; mucous membrane pale; meatus enlarged with scissors; Hegar's dilators. After introduction of No. 18, index finger was introduced, both having circumferences of 6 ctm. Diagnosis completed. No pain on cutting or dilating. Slight discomfort from stretching on introduction of finger far into bladder. Whether cocaine would be effectual in the removal of such a tumor yet remains for demonstration.

2. *Galvano-caustic division of the urethro-vaginal wall. Butaud* (loc. cit.) gives a case of a very susceptible patient. Chloroform contra-indicated on account of condition of kidneys and arteries. Calculus of urethra. Solution of 0.50 ctgm. cocaine to 5 gm. water used. Anterior vaginal wall, meatus, introitus, etc., pencilled repeatedly and same solution thrown into pocket containing calculus. Section of septum by heated platinum wire; lasted four to five minutes. No pain. No loss of blood.

3. *Excision, torsion, or cauterization of urethral caruncles; vegetations of meatus, polypi of meatus urinarius, prolapse of urethral mucous membrane, etc. Godson* (*British Medical Record*, January, 1885) quoted by Butaud, see original.

Butaud gives vascular vegetation of meatus urinarius, twenty per cent. solution of cocaine, twice pencilled on vegetations and surrounding parts. Excision, scissors; no pain; weaker solution of iodide probably answer.

Butaud (loc. cit.). Case 1: Pediculated vegetations of inferior lip of meatus; five per cent. solution of cocaine; cautery; no pain.

Case 2: Polypus of urethra, size of filbert, hung from meatus; ten per cent. solution of cocaine; torsion; thermo-cautery to seat of implantation; no pain. Sensation had returned in ten minutes.

Case 3: Two small urethral polypi hung from meatus, very painful; ten per cent. solution of cocaine. Anæsthesia in four minutes; excision, scissors; galvano-cautery, no pain. Sensation had completely returned in fifteen minutes. Under cocaine polypi blanched.

Fränkel (loc. cit.) recommends employment of cocaine in the treatment of superficially seated growth of vulva, condylomata, etc., and in caruncles of urethra.

Polk (Knapp, loc. cit.) recommends cocaine in removal of urethral caruncles; four per cent. solution of cocaine, med. cautery.

Emmet's "button-hole" operation.

Thomas (loc. cit.), painful and irritating inflammation of female urethra.

From the preceding enumeration of a few of the almost infinite number of conditions in which cocaine has been used as a local anæsthetic in gynecology, and with the thought before us that in obstetrics,[1] ophthalmology, laryngology, and general surgery the results of its application have been no less gratifying, it will be seen how great is the measure of its usefulness.

HUNGRY POLES.—Some Poles in Toledo came near creating a riot because the meat-inspector attempted to prevent them from eating the meat from a cow which had died of splenic fever.

[1] It may be [illegible] following articles. Knapp [illegible] quotes experiments of Le Fevre, an interne at Bellevue, with cocaine in the first stage of labor; Weiss (loc. cit.), Cocain gegen unstillbares Erbrechen der Schwangeren; Lucas, Del [illegible] de la [illegible] Paris, xvii. 163–169; also, Compt. Rend. Soc. de Biol., Paris, 1885, 8. S., ii., 37–40: Fränkel (loc. cit.), On Cocaine in First Stage of Labor; Uhler, Muriate of Cocaine in Labor, Maryland M. J., Baltimore, 1884–85, xii., 20: Cocaine in Completion of Second Stage of Labor. Hergott [illegible] De l'emploi de la cocaine en obstétrique. Hergott reports instances of usefulness of cocaine in fissured and painful nipples: Thomas (loc. cit.) refers to employment of cocaine in vomiting of pregnancy, and first and second stages of labor; Engelmann, Med. Rev. (loc. cit.), gives instance of success of application of four per cent. solution cocaine to eroded cervix in vomiting of pregnancy; Cincinnati Lancet and Clinic, etc., 1884, xiii., 552, The Use of Cocaine in Painful Catheterization after Labor; also the last number of the Nouvelles Archives [illegible]

A CONTRIBUTION TO THE SYMPTOMS AND PATHOLOGY OF ENDARTERITIS OBLITERANS.[1]

BY GEORGE L. PEABODY, M.D.,

[illegible] AND [illegible] NEW YORK.

My communication this evening concerns the details of a few cases that have recently been under my care, most of them with fatal termination, and followed by autopsies which rendered the lesions sufficiently plain. They are offered to the Society not as something new, but as bearing with some distinctness upon a chapter in special pathology upon which comparatively little work has been done—at least here. It is interesting that death may result from this lesion, with striking clinical evidences of destruction of motor areas in the brain, which autopsy reveals to be intact. The only explanation which suggests itself is that, in addition to the partial obliteration of the lumen of the nutrient artery of the area affected, there must have been a spasmodic contraction of the vessel or vessels which was sufficient to cause complete local arrest of the circulation. The duration of this spasmodic contraction varies. In some attacks it lasts only a few minutes, and then all the symptoms pass away as rapidly as they come. In others the duration is prolonged to such an extent that life comes to an end before it ceases; and yet the duration may not be sufficiently prolonged to cause softening of the brain-area affected.

Another possible termination is hemorrhage, as is seen in one of my cases.

This lesion is common enough in nearly all the organs of the body. I have frequently seen it in the lungs, kidneys, heart, and in neoplasms, especially in epitheliomata. It has been, however, in my experience, commoner in the brain than in any other organ. It needs not to be said that it does not always produce symptoms.

It was, at one time, supposed to be invariably due to syphilis, but that idea is now no longer held, although it is more common in syphilitics than in others.

The earlier writers on this subject—Steinburg, Heubner, Wilks, and others of more recent date—maintain its dependence upon syphilitic infection; but it has occurred in so many patients in whom no other evidence of that disease could be found, either clinically or anatomically, that it seems to me fair to admit that this cannot always be the case.

One of the first cases that came under my observation, some years ago, occurred in the person of a prominent surgeon of this city, who realized the necessity of giving a complete history of his life to his physician, and who had had a large family of healthy children. He certainly did not know that he was syphilitic. Other cases of this kind have come under my observation.

Hilton Fagge believed it to be always a lesion of syphilis.

The most recent writer on this subject of whom I have any knowledge is a Frenchman named Hippolyte Martin, who has an elaborate article in the *Revue de Médecine* for January of this year. He is quoted in the *Centralblatt f. kl. Medicin* for May 15, 1886.

In a very elaborate article he endeavors to prove that a large number of organic diseases are due to this arterial disease. He considers that it occurs earliest in the *vasa vasorum* of the ascending aorta, and regards alcohol, lead, and uric acid as efficient causes of the lesion. A great many cases are not susceptible of explanation, such as those which relate to young children of three or four years of age, who are affected neither by tuberculosis nor syphilis. He regards micro-organisms as an occasional cause. Certain trophic disturbances of the nervous system are also vaguely alluded to in reference to etiology. This disease in the aortic nutrient vessels may give rise to atheroma of the aorta. He ascribes the origin of many cases of hitherto unexplained mitral disease to this lesion in the arteries of the valve, as well as also degeneration of the heart-muscle and new-growths in it. Atrophic changes in the kidneys are thus produced. Similar changes occur in the spinal cord, and sclerosis of the posterior columns is instanced as one of the commonest of them.

Atheroma of the cerebral arteries is traced to progressive obliterating arteritis as a cause. We know but little of the consequences of this disease in the lungs, liver, spleen, alimentary canal, and skin, but cirrhotic changes in most of these organs are probably thus produced.

This paper by Martin is long, clearly written, and very suggestive.

The following cases have occurred to me during the past few months:

CASE I.—J. M——, aged fifty-six, a native of Ireland; widower; a tailor by occupation; was admitted to my service in the New York Hospital April 22, 1886. He gave the following history: His mother was rheumatic; his father he knew but little. He said that he (the patient) had had rheumatism in his hips for six years. He denied malarial history. He had a soft chancre years ago, and suppurating bubo, but he denied symptoms of syphilis. He has partaken immoderately of spirits for the past twelve years. During the entire past winter he has suffered from a continuous headache, and from ringing in the ears. He has not been dizzy. About ten days ago he suddenly fell to the floor, and was unable to move either of his right extremities, and was unable to talk; he did not lose consciousness. In half an hour he was able to talk, and power had returned in great measure to his leg, but less to his arm. Four or five times since then he has had slighter attacks of a similar character, when he could not speak or move, but recovered always in a few minutes. There was never any loss of consciousness. He never had an attack previously to ten days ago. His appetite is fair, his bowels regular. His temperature is 100.6°, respiration 24, and pulse 82, on his admission to the hospital at 11 A.M. He is senile; his superficial arteries are stiffened and tortuous. He is poorly nourished; there is no œdema. There is incomplete right facial paralysis. The tongue on being protruded deviates to the right. There is well-marked right hemiparesis; there is no disturbance of sensation; there is lateral curvature of the spine; the chest is barrel-shaped; the heart-sounds are normal.

His urine gives the following results on examination: Reddish-yellow, acid, 1.024, no albumen, negative microscopically.

Treatment.—Potass. iodid., gr. xx., every three hours.

April 23d, at 3 A.M.—He had a seizure at this time characterized by loud, gasping, stertorous breathing, and complete inability to speak or protrude his tongue. His pupils were normal. He could move both arms and legs, but there was marked diminution in the power of both of his right extremities. Consciousness was complete. In about half an hour he recovered from this attack, was able to speak perfectly, and told accurately all that had happened. He could protrude his tongue readily. It deviated somewhat to the right. His temperature and pulse were normal; his respiration somewhat accelerated. The iodide of potassium was increased to gr. xxx. at a dose. He felt well, and was allowed solid food at his own request. In the absence of the attendant he tried to get into bed from the night-stool this morning, but fell and was unable to get up without assistance. At 5.30 P.M. he had an attack similar to the previous one. It lasted forty minutes. Recovery from it was slower and less complete. He could soon protrude his tongue, but with difficulty. He could talk so as to be understood, but talking was an effort, and his speech was indistinct.

April 24th.—During the early part of the night he again got out of bed and fell, and was quite restless. He said that after both attacks his head ached very severely, and he was unable to eat. Very early this morning he had a similar attack, but much more severe than any of the previous ones. At 4.30 A.M. he was still suffering from

[1] Read at a meeting of the Practitioners' Society, on June 1, 1886.

it, was conscious, but now was entirely unable to move the right side.

At 9 A.M. he was unconscious, in a profuse perspiration, and breathing with marked stertor. His temperature was 104° F., respirations 52, pulse 129. He continued in this state, rapidly growing weaker, till 1.45 P.M., when he died. The temperature after death was 105.8° F.

The autopsy was made about an hour after death. The weather was warm, and therefore, to prevent the occurrence of post-mortem changes the body was taken directly from the ward to the autopsy-room. It was fairly nourished. Rigor mortis was absent. There was no œdema. The organs generally were normal. The cortices of the kidneys were a trifle thin, but the surfaces were smooth, and the markings distinct. There was slight hypertrophy of the left cardiac ventricle.

There was a mass of grayish-yellow material in the liver, measuring two by three centimetres. It contained caseous material, and proved on examination to be surrounded by a layer of connective tissue, and to be an old gumma.

With the exception of the brain, now to be described, the other organs were substantially normal.

The arteries in the circle of Willis showed several small, insignificant patches of atheroma. In most of them, notably the basilar and left middle cerebral, there was a well-marked growth of connective tissue from the wall of the intima. The calibre of the vessels was thus distinctly encroached upon, but by no means completely obliterated. In many of these regions was found the small-celled growth of periarteritis as well.

There was no alteration in the color or consistency of any part of the brain, and no other change was found.

A microscopic examination of the affected arteries showed the lesion to be a chronic endarteritis, *i.e.*, a connective-tissue growth from the intima, which involved to a varying degree almost the entire circumference of the vessel. The lumen was thus not obliterated, but very materially encroached upon.

I have the pleasure of showing you here the arteries in question, and also several microscopic sections of the left middle cerebral and basilar arteries. They are so very demonstrative as to need no detailed description.

CASE II.—R. O. H——, aged thirty-six, a stenographer, seen on January 26, 1886, with Drs. Franz Foerster and Schlegel, of this city. For several weeks prior to his illness he had complained of vague and indefinite pains in the occipital region, and of sharp lancinating pains on the right side of the head. He had been treated with quinine and phosphoric acid, with partial relief. On January 25th he worked steadily at his calling all day, ate a heavy supper at 7 P.M., and continued his work until 11 P.M., when he went to bed. At one o'clock next morning his wife was aroused by loud stertorous breathing, and found him sleeping so heavily that she became alarmed. After much effort she succeeded in arousing him, but not to a condition of consciousness. He was wildly delirious, raving like a madman, and endeavoring to force his way through the wall into the next house. His wife succeeded in persuading him to return to bed, and in a few moments he became profoundly comatose. From this condition of coma he was never again aroused. The doctor was summoned and found the temperature not elevated, pulse scarcely perceptible, respiration very shallow, pupils unevenly dilated. Under treatment his pulse improved, and his temperature rose to 100°. I saw him before noon on this day. He could not be roused, but when loudly spoken to and shaken his face would become distorted as if he were in pain, and he would bring his right hand to his head and groan. His pupils were normal and reacted well, and his pulse was 80 and feeble. He continued in this state all of that day and the next. His urine was suppressed for twenty-four hours, and then became fairly abundant and of normal characteristics.

During much of this time there was marked cutaneous hyperæsthesia, and there was never any paralysis. His pulse was never full and slow; his temperature rose to 101° shortly before death. On January 27th he grew steadily weaker, his coma became more profound, and he died at 10 P.M., forty-five hours after the commencement of the attack, respiration having ceased before the heart ceased to beat. Dr. Foerster tells me that the patient always considered himself syphilitic; but that he (the doctor) never satisfied himself that he was so. He was of very temperate habits.

The autopsy was made twelve hours and a half after death. Examination of the head only was allowed.

The pia was found intensely congested. Beginning at the optic commissure, and extending thence backward over the base of the brain, there was a thin layer of blood on the surface of the pia and in its meshes. Its point of greatest thickness was over the pons, where it measured 3 mm. It completely surrounded the basilar artery. The wall of the basilar artery was seen to be very thick, owing, as can still be seen, to a growth from the intima. This growth covers only a centimetre in length, and though it markedly diminished the lumen of the vessel it did not entirely obliterate it. There was marked softening with punctate hemorrhages in the right temporo-sphenoid lobe, and in much of the gray matter of both occipital lobes upon the vertex. The vessels at the base were otherwise normal. There was a little bloody serum in both lateral ventricles, and there were small, well-formed clots in the third and fourth ventricles.

The convolutions were not flattened.

The microscopic examination of the basilar artery at the site of the lesion revealed, combined, the evidences of a well-marked periarteritis and endarteritis obliterans. The lesions are both well seen in the sections which I lay before you here upon the microscope. The extensive, small-celled, moderately vascular growth surrounding the vessel exactly at the site of the connective-tissue growth from the intima would clearly account for marked interference with the lumen of the vessel.

This combination of lesions I have before recorded (in the "Transactions of the Pathological Society") in a patient who died after repeated attacks of well-marked cerebral syphilis, which frequently yielded completely to treatment. That patient died, after having persistently neglected treatment, in the fourth attack of cerebral symptoms; and in his case the combination of this periarteritis and endarteritis was situated in one of the fissures of Sylvius, and involved the middle cerebral artery, with the production of secondary softening in the floor of the corresponding lateral ventricle.

CASE III.—M. E——, aged eighty; Ireland; married; was admitted to my wards in the New York Hospital, May 30, 1885. She was brought in by the ambulance, with the history that she had been unconscious a week, having suddenly become so. On admission her temperature was 100.6°; respirations, 20; pulse, 100, at 2.30 P.M. She was in a condition of coma from which she could not be roused. There was complete paralysis of the left arm, incomplete paralysis of the leg of the same side. The extremities of the right side were rigid, and there were automatic movements of the right hand and arm. Reflexes were exaggerated on the right side and delayed on the left. Both pupils were slightly dilated, the right rather more so than the left, and they reacted sluggishly to light. Her tongue was dry and brown, and did not deviate. Her pulse was imperceptible, respiration shallow. Her urine was of low specific gravity, and contained albumen and casts, both hyaline and granular. She was unable to swallow, and an attempt was made to nourish her by enemata, but they were not retained. On May 31st her temperature had risen to 103.4°, and her respirations were 32, her pulse being 152. Her face was flushed, paralysis became more complete, the automatic movements of the right side had ceased,

and the rigidity had become more marked. Toward afternoon her pulse failed, and she grew progressively weaker, and at 4.30 P.M., twenty-six hours after she first came under observation, she died. Her temperature rose before death to 107°.

The autopsy was made twenty hours after death. The muscular tissue of the heart contained a little fat. The kidneys had many small cysts in the cortices, and the cortices were thin. The cortex of the brain showed the condition of senile atrophy usual at her age. The vessels at the base of the brain, and the two middle cerebral arteries, extending well into the fissures of Sylvius, showed the condition of obliterating arteritis. There was no alteration either in the color or consistency of the brain tissue, such as indicates softening.

CASE IV.—John M. B——, aged forty-five, a native of the United States, unmarried, a watchman by occupation, was admitted to my service in the New York Hospital, February 13, 1886. He was brought in by friends, who stated that he had been suddenly attacked that morning with convulsions, which were much more marked on the right side than on the left. At first he had vomited a large quantity of watery fluid. From that time until the time of his admission, at 3.50 P.M., the convulsive movements had been repeated to a slight extent occasionally. His friends also stated that he had suffered from rheumatism, and had complained from time to time of headache, dyspnœa on exertion, and some difficulty with his eyesight. His temperature on admission was 103°. Respiration was 22; pulse was 90. He was poorly nourished. There was no œdema. His superficial arteries were rigid and tortuous. There was rigidity and occasionally convulsive movements of the left extremities. There was slight right facial paralysis. Reflexes were normal, pupils also. He presented a senile appearance generally, and was probably really much older than his friends thought. Arcus senilis was marked. The heart-sounds were feeble, but there were no murmurs. There was complete amnesic aphasia. His urine was normal.

He was given potass. iodid., gr. xx., every three hours. At 9.30 P.M. his temperature had fallen to 100.4°.

The next day his temperature was normal all day. He passed his urine involuntarily during the night, and after the first dose was unable to swallow his medicine or to take any nourishment. During the night his medicine and food were both administered by rectum, but on the day following his admission he was able to swallow with ease. On the next evening his aphasia was gone and he became very noisy and delirious, and was given morphine hypodermatically without much effect.

On February 15th his delirium was again repeated at night. As his bowels had not moved, he was given calomel, and subsequently croton-oil, with the effect of producing one evacuation. His temperature that evening was 101°.

February 16th.—He was very noisy last night, and morphine (gr. ¼) again failed to quiet him when given hypodermatically. He imagined through the night that he was being devoured by rats, and was finally quieted only after four doses of digitalis, chloral, and bromide of potassium had been given at intervals of one hour. His iodide of potassium had been increased to forty grains every three hours.

February 17th.—His temperature varied between 98° and 101.2°. He was quiet most of the day, and was easily quieted to-night with much less medicine than he took last night.

February 18th.—He commenced to recover his memory, his mind became clearer, and he talked rationally. He still had to be catheterized at regular intervals. His urine continued normal.

February 19th.—Last night he passed urine without help. He remained perfectly quiet, and continued to be perfectly rational on most subjects. He was allowed soft diet.

February 20th.—Pulse, temperature, and respiration were normal.

February 21st.—He was allowed to get up and dress, and seemed to feel perfectly well. There was no trace of paralysis, and no return of aphasia.

February 24th.—Iodide of potassium was reduced to gr. xxx. t.i.d. He was now rational on all subjects, and presented no symptoms whatever, except that he was not very quick of apprehension.

February 26th.—He left the hospital apparently well.

Inasmuch as the patient recovered, there is, of course, room for doubt of diagnosis; but the course of his disease seemed *to me* to preclude the possibility of syphilitic pachymeningitis—the only other lesion at all to be considered.

Clinical Department.

GUN-SHOT WOUND OF KNEE JOINT—RECOVERY.

DR. JOHN RODMAN, of Abilene, Tex., reports the case of a man who was shot horizontally through the knee-joint with a "bull-dog" pistol, the ball ranging outward. A large quantity of synovia was evacuated, and as the joint was entered, the bone was found to be shattered, one spiculum of which was removed at the time the ball was spent by the bone, and was extracted from the fascia on the outer side. The probe grated over a large surface of comminuted bone, and came in contact with pieces of bone that could not, however, be removed through the wound. The latter was irrigated and cleansed with corrosive sublimate solution and hermetically sealed, a posterior splint being applied. The temperature was but 99⅘° on second day, and was normal on the fourth day and afterward. The dressing was removed fifteen days after the receipt of the injury, and no pus could be found. The joint is now being flexed daily, and the prospects are that no stiffness will result. Dr. Rodman says that in his past experience of knee-joint wounds (from railroad injuries solely), he has never known a recovery, even after amputation, when the joint was opened and the bone comminuted.

CONGENITAL TUMOR OF THE RECTUM.

DR. W. H. HAYNES, of 330 East Fourth Street, referring to a case of supposed congenital external piles, published in THE MEDICAL RECORD of November 22, 1884, writes that he has recently met with a somewhat similar condition. The patient, a female, the second child of a healthy mother, had from the day of its birth a tumor of the rectum.

After each stool there was seen projecting from the anus a globular tumor about the size of a small cherry-stone, dark red in color, suspended by a short pedicle from just above the muco-cutaneous border of the anus. No hemorrhage attended its appearance, and it was painless and semi-solid to the touch. It was seized with a pair of forceps, which caused slight bleeding. A silk ligature was tied around the pedicle at its base, and on the morning of the third day following, the tumor fell off during a stool, and was thrown away. When the child was seen a few days later there was nothing unusual to be noticed about the anus, except a little point of ulceration just within its border. There was no reason to suspect any predisposing influence other than that the mother was afflicted with internal hemorrhoids, but not to any great degree of suffering.

Dr. Haynes writes: "Objections may be raised to the term 'congenital hemorrhoids,' yet it certainly succinctly describes the conditions found in this case and the one before referred to, better than any other that could be

mentioned, although it may seem inconsistent to name a deformity after a disease, though they resemble each other in every respect except as to cause. Again, it may be thought that the last case was one of polypus of the rectum; but as to that I would reply that its location and appearance were certainly not that of the soft gelatinous polypi met with in children, nor of the hard fibrous tumors found in adult life, but it did resemble more than anything else what is termed hemorrhoids or piles. In neither case were the contents of the tumors noted. In the first they were not looked for, and in the other the tumor was lost."

AN ANODYNE FOR USE IN VESICAL IRRITATION.

Dr. W. P. Copeland, of Eufaula, Ala., writes: "In almost every community there are old men who suffer from enlarged prostates, accompanied with a chronic inflammation of the neck of the bladder, rendering them miserable sufferers and a care and anxiety to their friends and families. Having had the professional care of several of this class of cases, and dreading the tendency they so frequently incur by the administration of opium for the relief of pain, I resorted to various washes for injecting the bladder, resulting in my adopting a solution of benzoate of soda, ten grains to one ounce of water, with twenty to thirty drops of the green tincture of gelsemium; this is warmed and injected by the patient through a soft-rubber catheter, whenever the pain is severe, and the catheter withdrawn, leaving the medicine to be voided in twenty or thirty minutes; or where they are not able to pass anything from the bladder, the catheter is reintroduced and the medicine allowed to escape. My experience with this treatment has been so satisfactory that I cannot refrain from giving it publicity to the profession."

SOME OF THE THERAPEUTIC EFFECTS OF CAFFEINE WHEN HYPODERMATICALLY ADMINISTERED.

Dr. John Cochrane, of Lowell, Mass., writes that some two years ago, while seeking a preventive of the depressing effects sometimes noted after the administration of morphine, he became interested in the study of caffeine and its therapeutic value, and determined to test the assertion that caffeine increases the force of the heart and arterial tension. "During these two years," he writes, "I noted my cases, and from these notes select the following cases, because they prove conclusively to me that the above statement is correct:

"Case I.—A professional gentleman, aged forty-three; has suffered constantly during the last thirty years from intermittent fever and chronic rheumatism; he is addicted to the morphia habit, and during the greater part of the last sixteen years has been taking from one-fourth of a grain to twenty-five grains per diem, just as he felt inclined. He has repeatedly tried to give up the drug, and as often failed. During one of these struggles I found him suffering from excessive debility and wretchedness—thirst, anorexia, soreness in back and limbs, headache, eyes dull and pupils small, tongue flabby, dry, tremulous, and like raw beef; heart slow, weak, heaving; pulse, 72, weak, and almost imperceptible; respirations, 14, shallow, and interrupted every few moments by a half-gasp, half-sigh, as if the air escaped too quickly, and accompanied by a feeling of want of breath; temperature, 98.8° F. I dissolved one-half of a grain of caffeine in twenty minims of warm water and injected the solution into his arm. In half an hour the headache, irritability, soreness, dulness of eyes, and wretchedness had disappeared; the respirations were 16, full, deep, and uninterrupted; the heart was strong and steady; pulse, 84, large, strong, and full; temperature, 99.2° F.; the patient expressed his feeling by saying he felt 'like a well man.' These direct effects lasted between three and four hours. In the afternoon the same quantity of caffeine was injected, and followed by the same effects. There were several ill effects—excessive thirst, a craving for a renewal of the medicine, and next morning the sites of the injections showed signs of ulceration.

"Experience has led me to put the utmost confidence in caffeine as a synergist. The following case illustrates the value of the drug in this respect:

"Case II.—A professional gentleman, aged thirty-six, unmarried. Excepting cardiac weakness, caused by a severe and prolonged attack of rheumatic pericarditis sustained six years ago, the patient is in excellent health. But he has a habit of eating according to the mood he is in—sometimes he masticates slowly, and sometimes he 'bolts' his food. This bolting is followed by indigestion and colic. During the twenty months of my attendance he suffered from fifty-six such attacks. At first I administered sometimes morphia alone, at other times dissolved tablets of morphia, atropia, and sodic chlor.; relief from pain followed almost immediately, yet the exhaustion, occasionally amounting to collapse, and the indescribable wretchedness resulting from the remedy would be so great as to require a day's rest. In 1885 I began to use the following combination:

"℞. Pulv. caffeine et
Pulv. morphiæ sulph.....āā gr. ½.
Pulv. atropiæ sulph..... gr. $\frac{1}{100}$.
Aq. camph..... ℥ xx.
"M.

"This was employed more than twenty times, and succeeded in every instance, a second injection being required on only three occasions. Excepting intense thirst, the patient felt relief as quickly and more satisfactorily than by the former combination; the heart beats stronger and steadier, collapse and wretchedness never followed, and in about twenty minutes he would resume his duties, and, what is more satisfactory in his case, his dislike to morphia is intensified on account of the thirst induced. With all my other patients I have succeeded as well, and I take care to order grs. iij. of caffeine, with a seidlitz, to be taken three hours after the injection; this clears the alimentary canal and sustains the nervous system.

"Case III.—A youth, aged eighteen, laborer; general health excellent until rheumatic fever set in. I found the patient prone, helpless, and moaning piteously on account of pain in his joints and the præcordial region. Auscultation revealed peri- and endo-carditis; the pulse was 156, small, weak, and intermittent; respirations, 60, shallow and gasping; temperature, 106° F. Twenty minutes after injecting the caffeine mixture the patient was helped to place himself where he could lean against several pillows, and then declared himself as feeling 'just splendid.' The pain, irritability, and dyspnœa had disappeared; the heart beat steadily and strongly, the pulse fell to 120, and in twenty minutes more the patient was sound asleep. So greatly was he relieved that he insisted upon having the remedy administered hypodermatically every night throughout his illness.

"I have treated several cases of acute rheumatism since then, and each has been as signally benefited by this auxiliary, *especially when there were signs of cardiac failure.*

"I have repeatedly used this combination in cases of hysteria, of convulsions in infants and children who were teething or suffering from meningeal irritation, etc., with the best results. In acute alcoholic mania, when the heart begins to falter on account of the duration of the insanity and its concomitants, I cannot speak too highly either of its power to stimulate the heart or of its calmative co-operation with morphia, while maintaining the nervous system and so preventing dangerous symptoms.

"Case IV.—Lastly, I will speak of one case more, to show that the patient's feelings and belief have no influence on the therapeutic action of the drug. The patient

is an elderly lady who suffers from incidental chronic traumatic stricture of the bowel. At the time of which I speak she was suffering intense pain. A few minutes before I called she had dismissed a quack, who styled himself 'a metaphysician,' because, after four hours' praying, he had failed to relieve her. To test whether her confidence in the 'regular' treatment was as strong as she claimed, I injected ten drops of pure water. In a few moments she declared herself much easier; in five minutes more she expressed pleasure at the great relief she was experiencing. Now, that she really suffered, the vomited matters and pulse showed; but she believed I had injected the caffeine compound as usual, and, as she is sometimes so ill that a repetition of the remedy is required, I told her she must have a second dose to insure a night's rest. Two minutes after injecting the mixture she said she felt strangely, which feeling merged into giddiness. In five minutes more the pulse had lost its usual intermittency and became stronger and slower, the body grew warmer, intense thirst set in, and the patient soon went to sleep.

"A perusal of the foregoing cases must force any reasonable person to acknowledge that, in a general way they prove that caffeine, or a compound containing caffeine as a synergist, does, indirectly, make the injection of morphia a safe proceeding, and directly 'increases the force of the heart and arterial tension.'"

Progress of Medical Science.

Aconite in the Fevers of Childhood.—Dr. W. Barrett Roué, writing in the *Provincial Medical Journal* of May 1, 1886, complains that English physicians make too little use of aconite in the febrile affections of childhood, and urges its more general employment. He gives it in small and frequently repeated doses (one-fourth to one-half minim of the tincture every three or four hours for children three or four years old), combining it with tincture of belladonna (one to two minims) to prevent depression. As soon as the child perspires freely, the medicine has done its work and should be stopped, to be again employed if there be a further rise of temperature. In cases of more than usual prostration he combines the aconite with carbonate of ammonia, and accompanies the mixture with brandy. The aconite, he says, will act equally well in such a combination, and there is nothing unscientific in so prescribing it.

Intra-pericardial Rupture of the Aorta.—Professor E. Winge reports the following case in the *Norsk Magazin for Lægevidenskaben* for June, 1886. The patient, a man fifty-four years of age, had had apoplexy sixteen years before, but had made a perfect recovery. He had had a little malaise and complained of indefinite pains in the shoulder for a few days, but had exhibited no grave symptoms up to the moment when he dropped dead. At the autopsy the pericardium was found distended with blood, and in the connective tissue, between the origins of the pulmonary artery and the aorta, was found a sinus, filled with blood, through which a probe could be passed into the aorta. The intima of the ascending portion of the aorta was found atheromatous and scattered over with numerous ulcerated or calcified spots. The heart was the seat of excentric hypertrophy, the valves and coronary arteries were normal, and the cardiac muscle was pale but not fatty degenerated.

The Physiological Effects of Massage.—Dr. F. Gopadze has published a series of observations undertaken with a view to determine the effect of massage on the transformation of the nitrogenous principles of food. Though there has been a general tendency among authors to assume that massage increases the assimilative power, no exact observations on the subject have hitherto been published. The author conducted his experiments upon four medical students, who for three consecutive weeks became inmates of Professor Manassein's clinic, and lived on certain articles of food—bread, milk, soup, veal, and roast beef, the quantities ingested being accurately noted. The nitrogen in all the samples of food, and in the fæces and urine excreted, was determined by the Kjeldahl-Borodin process. Massage was practised for from twenty to twenty-five minutes once a day, two or three hours after food. The operations were commenced by *effleurage*, beginning from the extremities and working toward the centre. This was followed by *massage à friction, pétrissage, tapotement*, a second *effleurage* of each part concluding the whole. In all four cases the appetite was decidedly increased, not only during the week in which massage had been practised, but after it had been stopped. The amount of nitrogenous transformation was also augmented during the continuance of massage in all four cases. The augmentation persisted in two of the cases, but in the other two the transformation was less during the third than during the first week. The quantity of nitrogen assimilated increased in all four cases, independently of the amount of food ingested. During massage two of the subjects gained slightly in weight, the other two losing weight; but during the week following the one in which massage was practised all four gained. The axillary temperature decreased, for about half an hour after the operation, to an extent varying from 0.1° to 0.5° C., after which it began to rise, attaining its original figure, or from 0.1° to 0.3° below it, about an hour after the end of the *séance*. The respirations became more frequent, and were of a deeper character. The effect on the pulse varied with the character of the massage. When this was carried on lightly, the pulse became more frequent; but when the manipulation was more forcible, the pulse became slower. The effects in both cases persisted for an hour or more after the termination of the operation. In conclusion, the author suggests that massage should prove useful in chronic gastro-intestinal catarrh, in chronic constipation due to an atonic condition of the intestines, also in various cases where there is a lack of tone in the abdominal muscles.—*The Lancet*, May 22, 1886.

The Relation of Osteomyelitis to Ulceration.—In a paper read before the Surgical Society of Paris, M. Lannelongue said that one of his horses had had an enormous swelling over the frontal region, accompanied by suppuration, and speedily followed by grave constitutional symptoms and death. The appearance of the disease was preceded by an ulceration in the buccal cavity. This occurrence led the author to examine carefully the bodies of all children brought to him with the commencing symptoms of osteomyelitis, and he found in all cases superficial ulcerations, either of ecthyma or of eczema, on some part of the body. These ulcerations usually preceded the declared symptoms of osteomyelitis by a period of one to three weeks. The speaker thought that possibly these abrasions were the portals through which the specific micro-organisms gained entrance.

Treatment of Glaucoma without Operation.—At the meeting of the Académie de Médecine de Paris of June 15, 1886, M. Panas read a paper on this subject, the conclusions of which were as follows: 1. Myotic collyria, hitherto regarded as simple palliatives, may, in certain forms of glaucoma, be regarded as veritable curative agents. 2. The varieties of the affection which seem to be most benefited by these agents are precisely those in which operation alone (iridectomy or sclerotomy) is often ineffectual. 3. To obtain the best results from myotics, it is necessary to continue their use for a more or less extended period of time. 4. These remedies, in fine, constitute one of the most effective means which we possess for arresting the onward course of the glaucomatous process, when operation has been shown to be powerless to effect this. The author hoped that others would test the efficacy of myotics in glaucoma, and would report the results obtained.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, July 17, 1886.

A NEW MODE OF APPLICATION OF THE PLASTER JACKET IN THE TREATMENT OF SCOLIOSIS.

THE treatment of lateral curvature of the spine is one of the most thankless and unsatisfactory tasks which the surgeon is called upon to undertake, and we venture to say that there are few practitioners of experience who assume with any confidence the management of a case of this nature. The prognosis must always be guarded; the most that can usually be hoped for is that the progress of the deformity will be arrested, and he would be rash indeed who would promise to correct absolutely a true, so-called rotary, lateral curvature of the spine.

Considerable advances have, it is true, been made in the therapeutics of this affection within the past few years. The cumbersome, and sometimes even cruel, forms of apparatus, in common use a decade or two ago, have been very generally discarded, and figure at the present time only in the illustrated catalogues of the instrument-makers. Their place is now taken by some light and comfortably fitted instrument, or by the plaster-of-Paris jacket, and reliance is chiefly placed upon active or passive exercises designed to increase the lateral flexibility of the spine, the mechanical support serving merely to hold the patient in the improved position acquired through these exercises. But, notwithstanding these improved methods of treatment, we are yet far from the attainment of our end—far, that is, from the cure—and not the simple arrest of the onward course of this unsightly deformity. For this reason it is interesting to note the new methods of treatment proposed from time to time, and to read the reports of cures thereby obtained in a marvellously short period by their enthusiastic advocates. And even though experience usually serves to justify our scepticism concerning the real curative value of the proposed methods, we are nevertheless encouraged to recognize some of them as steps in the right direction and as sign-posts guiding us to a more rational system of mechanical therapeutics.

We find in the *Wiener Medizinische Wochenschrift* of May 8, 1886, the details of a modification by Dr. Alexander Fraenkel in the mode of application of the plaster-of-Paris corset, which seems, theoretically, to be a real improvement, but of which it is, of course, too early to speak with any confidence. The writer argues that the treatment of lateral curvature should be conducted on the same plan as that of club-foot, that it is not sufficient to place the vertebral column nearly, or quite, straight, but that the deformity should be over-corrected before the spine is immobilized. The first part of the treatment consists in passive exercises, designed to overcome the abnormal rigidity of the curve to such an extent that the spine can be forced into the reverse position. This is effected in the case of children by placing the point of greatest convexity of the primary curve over the thigh and bending the trunk above and below forcibly downward, in the same manner that one would straighten a bent stick across the knee. Daily séances of these manipulations, of about half an hour each, extended through one or two weeks, are usually sufficient, Dr. Fraenkel says, to render the spine fairly flexible. When this has been accomplished, the time has come for the application of the plaster jacket. The patient is suspended, as in Sayre's method, the hips are firmly fixed, and then two loops of strong bandage are passed around the body, resting against the apices of the primary and secondary curves. In order to avoid pressure-sores the convexities of the curves are well padded. Two assistants, one on either side, now make firm traction on the bandage loops so as to pull the curves in the opposite direction, and the plaster-of-Paris is then applied so as to retain the spine in this position of over-correction. The author does not favor a removable corset, but prefers a frequent reapplication of the plaster, opportunity being taken at each renewal to resume the passive movements.

A somewhat similar method has been proposed by Petersen in Langenbeck's *Archiv*, Heft i. Bd. 32. He places the patient in a position of lateral suspension in Barwell's sling, the weight of the body acting as the correcting force. This plan does away with the necessity of so many assistants, but it is evident that a less efficient force can be thus brought to bear upon the scoliosed spine than when lateral traction is made by bands.

Fraenkel says that his success thus far has been encouraging, though the method is too young as yet to be judged by its results. It is, of course, only applicable to comparatively recent cases, or rather to those cases in which, whatever the degree or age of the curve, the lateral flexibility of the spine is still present. Old cases of scoliosis, in which extensive alterations have taken place in the shape of the bones, and in which the vertebræ are so soldered together that the spine is as rigid as a solid bar, unfortunately are, and always will be, beyond the possibility of rectification.

NARCEINE IN WHOOPING-COUGH.

AT a recent meeting of the Société de Biologie, MM. Brown-Séquard, Laborde, and d'Arsonval united in praising the effects of narceine in whooping-cough and chronic bronchitis with hypersecretion. Narceine, $C_{23}H_{29}NO_9$, is one of the alkaloids of opium, but exists in it to a very small amount, at most not over 0.02 per cent. Most investigators agree that in its action upon man it resembles morphine, but is milder and causes no excitement. Claude Bernard first called attention to it by his assertion that it was a safer and more agreeable drug than morphine, but had about the same sedative and anodyne effects. Narceine was carefully tried by several Phila-

delphia physicians, some fifteen years ago, and they concluded that it was almost inert, even in doses of from one to five grains. Froumüller states that he has given twenty grains with no effect. On the other hand, many Continental physicians (Rabuteau, Behier, Debout, Eulenburg, Liné, and Laborde) have found that in doses of one-half to one grain it causes quietude and sleep.

The testimony heretofore has been so conflicting that doubts have arisen as to whether the same alkaloid has been used. M. Laborde now says that a very easy test of its purity is to add to the solution a drop of muriatic acid, when a beautiful blue color is produced.

Surprisingly quick results in whooping-cough have been observed by the French physicians above mentioned. The best mode of administration is to make a solution in syrup, so that a teaspoonful represents one centigramme of the drug. This is the minimum dose for children, the average dose being from 2½ to 5 centigrammes.

AN AMERICAN CONTRIBUTION TO BACTERIOLOGY.

Dr. J. W. McLaughlin, of Austin, Tex., has been carrying on a series of experiments in order to determine the nature of dengue, a disease which prevailed epidemically throughout Texas in the fall of 1885. As dengue presents all the clinical characters of an infectious disease, Dr. McLaughlin's researches were designed to discover, if possible, the presence of a parasite. The exceedingly difficult nature of the task in question was fully realized by the investigator; and we are glad to say that the details given of his work show him to be thoroughly imbued with the spirit of the careful searcher after truth. Dr. McLaughlin's work, carried on amid all the difficulties that attend one engaged in active practice, deserves the attention, and should awaken the pride, of every American physician; for he has shown, as Koch did, that after all, leisure, money, and elaborate appliances are not absolutely necessary for scientific work, and that the general practitioner who folds his hands and says he has no time for anything but practice, is really handicapped not so much by his surroundings as by his own indisposition.

Dr. McLaughlin, so far as we can judge by his report (*Journal of the American Medical Association*, June 19, 1886), used all the numberless precautions necessary in investigating the nature of the blood of dengue patients. He examined microscopically fresh specimens, as well as others that were dried and stained, and sterilized. He also obtained pure cultures of a micro-organism, and watched its growth in successive cultivations.

He believes that there is always in the blood of these patients a peculiar micro-organism, having its own method of growth, and taking up with especial avidity a stain of methyl-blue dissolved in caustic potash. This micro-organism is spherical in shape, and about $\frac{1}{2\,5\,0}$ to $\frac{1}{3\,5\,0}$ the diameter of a red blood-cell. The organisms grew well upon sterilized jelly, always preserving their morphological character in successive cultures. All the experiments seemed to show that the blood of persons suffering from dengue contains these micro-organisms, and no other.

Inoculations of the pure cultures were not made, apparently, and this seems strange, since dengue is a mild disease, and there should be no difficulty in finding subjects of experiment. It cannot be said either that this micrococcus is not identical with that found in other diseases. Dr. McLaughlin's experiments, therefore, are not conclusive of anything, as yet, but they furnish an important stepping stone for further research. Dr. McLaughlin has come quite near being the first American physician to find the specific micro-organism of a disease affecting man. American investigation, so far, has been confined to imitating the work of European investigators.

ICE-CREAM POISONING.

The summer season has been ushered in by numerously reported cases of poisoning from eating ice-cream. The two most important instances are those which have occurred in Michigan and in New Jersey. In the latter case, a large number of persons were attacked, shortly after partaking of the cream, with all the symptoms of a gastro-enteric irritant poisoning. The clinical aspect of the cases strongly suggested arsenic. There is some reason to suppose (so say the daily papers) that the cream was tampered with by persons having criminal intent. Several parties are under suspicion, and a legal inquiry is now in progress.

In the Michigan case, over one hundred and forty persons exhibited symptoms of irritant poisoning after having eaten the cream. A portion of the latter was sent for analysis to Professor Vaughn, of Michigan University. He reports, it is said, an important discovery made during his tests. He says that he had a short time previously isolated an active element in poisonous cheese. This substance he has named tyrotoxicon. He says, also, that traces of this body were present in the suspected ice-cream, and that to it, in his opinion, were the irritant symptoms due. On this assumption it is claimed that tyrotoxicon is due to the decomposition of milk, and may be developed in any milk kept in unclean vessels, or in an unwholesome atmosphere. The germ giving rise to this new product seems to propagate very rapidly, and as is the case with all other similar organisms, a small amount will speedily infect a large body of milk.

A very important fact, and one of great medical interest, is implied in the foregoing. It may account for much of the intestinal disturbance in children during the warm weather, notably cholera infantum, and kindred conditions. Professor Vaughn's report to the State Board of Health will be awaited with interest.

REORGANIZATION OF THE OUT-DOOR DEPARTMENT OF BELLEVUE HOSPITAL.

Despite the increase in other hospitals, Bellevue continues to be by far the largest institution in the city, or country, for the treatment of acute diseases, and it is still regarded by the colleges as the most important centre for clinical teaching. The hospital has provision for 1,200 beds, the actual number being 800, and it treats in its wards nearly twelve thousand patients (in 1885, 11,894) annually, while its out-door department each year relieves 33,000 persons.

Realizing the importance to the colleges of the hospital, the commissioners, some years ago, established the rule which gives an equal representation on the Medical and Visiting Board to each of the three large colleges,

and to the non-collegiate portion of the profession. The out-door department of the hospital, however, has not been so divided, but has been practically in the control of one college.

At a recent meeting of the commissioners, the Medical Board of the hospital was requested to draw up a plan of reorganization of this out-door department, which plan should place it under the control of the Hospital Board, and give to each college, and to the non-collegiate division, an equal share in the appointments at the dispensary. Such a plan has been drawn up, and will, we understand, soon go into effect. The result will be not only to give a just distribution of the clinical material, but the non-collegiate division of the Hospital Board, which represents, in part, the post-graduate school and polyclinic, has also its share. The result of the reorganization will, it is hoped, be a greater activity and efficiency in attending to the patients, and a juster distribution and more satisfactory use of the clinical material.

FEHLING'S TEST AS A REAGENT.

Of the various tests for sugar in urine the copper solution of Fehling has become popular on account of its simplicity and general reliability. Undoubtedly, the best form for using this test is the preparation made by Squibb, of Brooklyn, which is made in proportions recommended by Sutton in his work on "Volumetric Analysis," where each cubic centimetre under definite conditions is equal to 5 milligrammes of glucose; hence the 2 c.c. used for the testing are equivalent to 0.01 gramme of glucose, and that amount in 1 c.c. of urine is just one per cent. The two solutions, which are sold separate and accurately prepared, enable the tests to be used both qualitatively and quantitatively. The latter, however, is only roughly approximative, but still indicating 1 per cent., 0.25 per cent., and 0.1 per cent., according to the color shown and behavior of deposit. These results are sufficiently accurate for all practical purposes, and may be used at the bedside.

We now notice in a contemporary that a new use of Fehling's test-liquor has been suggested. It is said that if 1 c.c. of the test is mixed with 8 to 10 c.c. of urine, shaken up and boiled, and the fluid remain blue, nothing is indicated; but if decolorized with a pale yellow, flocculent precipitate, *peptone* is indicated. If the liquid turns orange and there is an orange precipitate, of course we have glucose.

If equal parts of Fehling's liquor and urine are mixed in a test-tube and boiled, and the clear liquid remain blue, there is little uric acid. If it becomes green, the urine contains an excess of uric acid or of a urate. If the precipitate is scanty, there is little phosphoric acid, but if copious phosphoric acid is present in excess. If these new reactions of Fehling's test be confirmed, they will undoubtedly prove of interest to the uroscopist.

The Attempt in this City to inoculate a boy who had been bitten by a rabid dog, with the preventive virus, has, it is said, been given up. Several inoculations were made by Dr. V. Mott, but the boy began to show such severe nervous symptoms that it was thought wise to discontinue the treatment.

News of the Week.

A Hasty Indorsement.—At the last meeting of the American Medical Association the following resolution was adopted by a majority of 159 to 106: "*Resolved*, That cremation or incineration of the dead has become a sanitary necessity in populous cities, and that this Association advises its adoption." This is an example of the hasty and careless action which too often characterizes our societies. While cremation is an excellent thing for those who like it, it has not yet been demonstrated that it is "a sanitary necessity in populous cities." The cremationists have not yet been able to trace a disease, much less an epidemic, to the suburban graveyards of our populous cities. We have always commended the practice of cremation as an advance in sanitation, but it is too soon to call it a necessity.

Dr. John B. Hamilton, Supervising Surgeon-General of the United States Marine Hospital service, has accepted the Professorship of Surgery in the Chicago Polyclinic.

The Emperor of Brazil has commissioned M. le Dr. Ferreira dos Santos, of Rio Janeiro, to proceed to Paris and study Pasteur's method, for the purpose of establishing later an institute in Brazil.

Cremation on Long Island.—Since December 4, 1885, there have been forty-five bodies cremated at the Crematory of the New York Society, Fresh Pond, L. I.

The Fight against the Microbe Theory.—At the meeting of the Académie de Médecine, some weeks ago, Professor Le Fort strongly attacked the microbists, and referred to the experiments of Rose, of Zürich, who left amputated surfaces exposed to the atmosphere, *et aux fureurs de tous les microbes*, without appreciable detriment to his patients, and contrasted it with that of Billroth, who, with identical hygienic conditions, had results less fortunate, although he invoked every possible antiseptic precaution. He also stated that he had tried similar experiments, having left two stumps—one at *Beaufort* and the other at *Hôtel Dieu*—entirely unprotected for several days, without the slightest interruption of the process of cicatrization or the development of any constitutional disturbance.

Medical Progress in Chicago.—Dr. Gregory writes to the *Medical Press* of Western New York his impressions on visiting Chicago after a six years' absence. He says: "In the six years last past the medical element of Chicago has developed beyond the stage of personal gain, and reached that of public benefit. Physicians there are not now telling of the number of prescriptions written in a day, so much as they are detailing anomalous conditions met with. To be sure, even a professional man, breathing a truly professional spirit, cannot live in Chicago without becoming imbued with a business fervor; consequently nearly all physicians have a down-town office as well as one at their residence. This peculiarity is very noticeable, as sometimes as many as twenty-five physicians are grouped in down-town offices over a drug store. St. Louis is the only other city

where this concentration of physicians' offices downtown and over drug-stores occurs so conspicuously. While in this feature Chicago differs from Eastern medical centres, she now resembles them in multiplied agencies through which physicians render the public gratuitous service. Six medical societies and an unknown number of clubs are maintained, and eight medical journals are published in the city. With this mass of public work and the large number of men thus engaged, it must be evident that a far different professional spirit would be engendered than without such agencies. Chicago must therefore be recognized as the medical centre of the West. Undoubtedly one of the agencies tending to produce this result is the State medical law, for in marked contrast to its previous condition is the present absence of charlatan advertisers and nostrum doctors."

A CHRONOMETER for measuring the swiftness of nerve-impulses has been devised by M. D. Arsonval. It is said that it can be easily managed by the clinician or practitioner.

"PROGRESS" is the title of a new monthly medical journal edited by the experienced journalist, Dr. Dudley S. Reynolds, and published in Louisville, Ky.

A "NEW" TREATMENT FOR GONORRHŒA. Dr. Edward Warren Bey, writes to *Gaillard's Medical Journal*: "There has been a new departure announced in the treatment of that opprobrium of the profession, *gonorrhœa*. Dr. Bourgeois, in an article published in *The Archives of Military Medicine and Pharmacy*, takes the position that the discovery of the special *microbe* of this disease furnishes the indication for its specific and certain cure. The problem resolves itself into the task of finding some topical agent sufficiently energetic to destroy the parasite without irritating the urethra. There are three such agents, according to Dr. Bourgeois' experience, viz.: permanganate of potash, bichloride of mercury, and sulphate of quinine—the first of which he employs in a solution of 1 to 2,000, the second in a solution of 1 to 20,000, and the third in a solution of 1 to 100. He recommends that these solutions shall be first warmed, and then injected in such a way as to reach every portion of the urethra four times daily—the last injection being made invariably at midnight, so that the *microbes* may not have time to reproduce themselves. Internally, he administers from one to two grammes of bromide of potash, and in scrofulous cases he supplements it with a daily dose of cod-liver oil and the potassic tartrate of iron. According to his statements, the disease is more rapidly and permanently cured by this treatment than by any other—the special indication being the destruction of the gonorrhœal gonococcus, and its elimination from the urethra.

LISTER'S LATEST ANTISEPTIC DRESSING.—A correspondent of the *Canadian Practitioner* writes: "It may be news to a great many to learn that Lister has discarded the use of the spray almost entirely. He now uses salalembroth exclusively in his wards for dressings, and it has so far given very fine results. It is a double mercurial salt formed by the sublimation of a mixture of perchloride of mercury and chloride of ammonium, and is exceedingly soluble. The salt was known to the alchemists, but has not been used in medicine in modern times. Lister prepares all his dressings now with a 1 to 100 solution of this—gauze, cotton-wool, lint, bandages, draw sheets, and where the wound is covered by the shirt it is rendered aseptic by dipping it in the solution and drying before the fire. To make any of these dressings, all that is necessary is to soak them in this solution and dry. Not being volatile, it does not require to be kept sealed in tin cases. He also colors these dressings with aniline blue 1 to 10,000; the benefit to be derived from this is that wherever an alkaline discharge comes in contact with the dressing the blue is removed and turns reddish, enabling one at once to see where the discharge has been, if the quantity was ever so small and had dried up before the dressing was removed. There is one precaution in using this dressing, and that is this: the dressing being dry and frequently handled might have some septic matter from bedclothes, hands, etc., so he always dips it in 1 to 2,000 perchloride just before applying it. He is making a salalembroth protective, which will be surcharged with the antiseptic, so that as a discharge comes through a dressing it will come in contact with this protective and can be kept aseptic."

THE ASSOCIATION OF AMERICAN PHYSICIANS.—The *Journal of the American Medical Association* makes a long attack upon The Association of American Physicians and Pathologists, and alludes very sarcastically to the "so-called American Ophthalmological, Otological, and Gynecological Societies." Its Washington correspondent questions the right of a hundred medical men to associate themselves together and call themselves The Association of American Physicians, and he asks if "the American Medical Association is to be degraded by a set of men in its own ranks?" At the same time the *Journal* says that it is not prompted by any feeling of opposition to the new Association, only it wishes it to sail under its own flag. The tone of the article is one of petulance and ill-will. It is not creditable to the *Journal*. The "so-called gynecological" and other associations do not need defence, however, any more than they deserved attacks.

A CURIOUS CASE OF MEDICAL ADVERTISING was brought up for the consideration of the Medical Society of North Carolina at its last annual meeting. It seems that Dr. Oscar Gregory, a physician who had been in good standing, moved to the town of Oxford, N. C., and having prepared to practise in that locality, he had printed a number of handbills setting forth the date and place of his graduation, the various positions of distinction he had held, the length of time of his professional services, concluding with the announcement that, "having always enjoyed a liberal patronage from every community in which he has lived, he is encouraged to hope for the same from Oxford, where he has determined to make his permanent home. Charges will be the same as those of the physicians of Oxford. He also claims to possess that charity for which his profession has always been so justly distinguished." The Board of Censors having charged him with violating Section I., Article 2, of the Code of Ethics, Dr. Gregory replies defending his course; he says, "I had not read the Code in some time before the circulation of the advertisement to which I

suppose you refer. But, after a careful perusal of the section mentioned, I fail now to perceive how the freest rendering of it prohibits a doctor from placing before a new community his proper credentials as a physician. I conceive, if this is not his privilege, he has no right to ask the patronage of that public. If, however, you, as the Board of Censors, interpret it, thus, I submit, and would be glad to have the specific infraction explained to me." The Board refused to consider Dr. Gregory's explanation tenable, holding that the issuing of handbills was not permissible under a just interpretation of the Code. The Society very properly sustained the Board.
